29	hols	R/W	0h	High or Low Signal This field indicates the position of the sub-panel based on the LPPT value 0 = Default Pixel Data lines are at the top of the screen and the active video lines are at the bottom of the screen 1 = Active video lines are at the top of the screen and Default Pixel Data lines are at the bottom of the screen
28-26	Reserved	R/W	0h	
25-16	lppt	R/W	0h	Line Per Panel Threshold Encoded value (programmed value range of {0:2047} represents an actual range of {1:2048}) used to specify the number of lines on the bottom part of the panel Bit10 of this field is in RASTER_SUBPANEL2 Hols determines whether Default Pixel Data is on the top (hols='0') or on the bottom (hols='1') Lppt defines the number of lines on the bottom part of the output
15-0	dpdlsb	R/W	0h	Default Pixel Data LSB[15:0] DPD defines the default value of the pixel data sent to the panel for the lines until LPPT is reach or after passing LPPT

### 13.5.15 RASTER\_SUBPANEL2 Register (offset = 3Ch) [reset = 0h]

RASTER\_SUBPANEL2 is shown in [Figure 13-33](#) and described in [Table 13-28](#).

**Figure 13-33. RASTER\_SUBPANEL2 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 13-28. RASTER\_SUBPANEL2 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-9	Reserved	R	0h	
8	lppt_b10	R/W	0h	Lines Per Panel Threshold Bit 10 This register is Bit 10 of the lppt field in RASTER_SUBPANEL
7-0	dpdmsb	R/W	0h	Default Pixel Data MSB [23:16] DPD defines the default value of the pixel data sent to the panel for the lines until LPPT is reached or after passing the LPPT

### 13.5.16 LCDDMA\_CTRL Register (offset = 40h) [reset = 0h]

LCDDMA\_CTRL is shown in [Figure 13-34](#) and described in [Table 13-29](#).

**Figure 13-34. LCDDMA\_CTRL Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

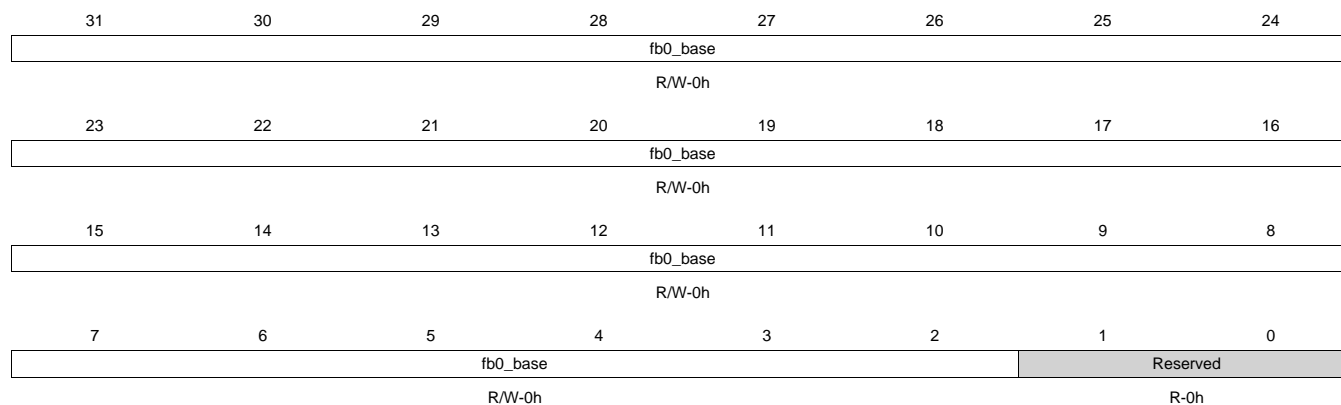

**Table 13-29. LCDDMA\_CTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-19	Reserved	R/W	0h	
18-16	dma_master_prio	R/W	0h	Priority for the L3 OCP Master Bus
15-11	Reserved	R/W	0h	
10-8	th_fifo_ready	R/W	0h	DMA FIFO threshold The DMA FIFO becomes ready when the number of words specified by this register from the frame buffer have been loaded 000 = 8 001 = 16 010 = 32 011 = 64 100 = 128 101 = 256 110 = 512 111 = reserved
7	Reserved	R/W	0h	
6-4	burst_size	R/W	0h	Burst Size setting for DMA transfers (all DMA transfers are 32 bits wide): 000 = burst size of 1 001 = burst size of 2 010 = burst size of 4 011 = burst size of 8 100 = burst size of 16 101 = N/A 110 = N/A 111 = N/A burst_size cannot be changed once the DMA is enabled in LIDD or Raster modes In this case, the DMA must be disabled and the Done Interrupt must occur before the value in this register can be changed
3	byte_swap	R/W	0h	This bit controls the bytelane ordering of the data on the output of the DMA module It works in conjunction with the big-endian bit See the big-endian description for configuration guidelines
2	Reserved	R	0h	
1	bigendian	R/W	0h	Big Endian Enable Use this bit when the processor is operating in Big Endian mode AND writes to the frame buffer(s) are less than 32 bits wide Only in this scenario do we need to change the byte alignment for data coming into the FIFO from the frame buffer(s) 0 = Big Endian data reordering disabled 1 = Big Endian data reordering enabled
0	frame_mode	R/W	0h	Frame Mode 0 = one frame buffer (FB0 only) used 1 = two frame buffers used DMA ping-pongs between FB0 and FB1 in this mode

### 13.5.17 LCDDMA\_FB0\_BASE Register (offset = 44h) [reset = 0h]

LCDDMA\_FB0\_BASE is shown in [Figure 13-35](#) and described in [Table 13-30](#).

**Figure 13-35. LCDDMA\_FB0\_BASE Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

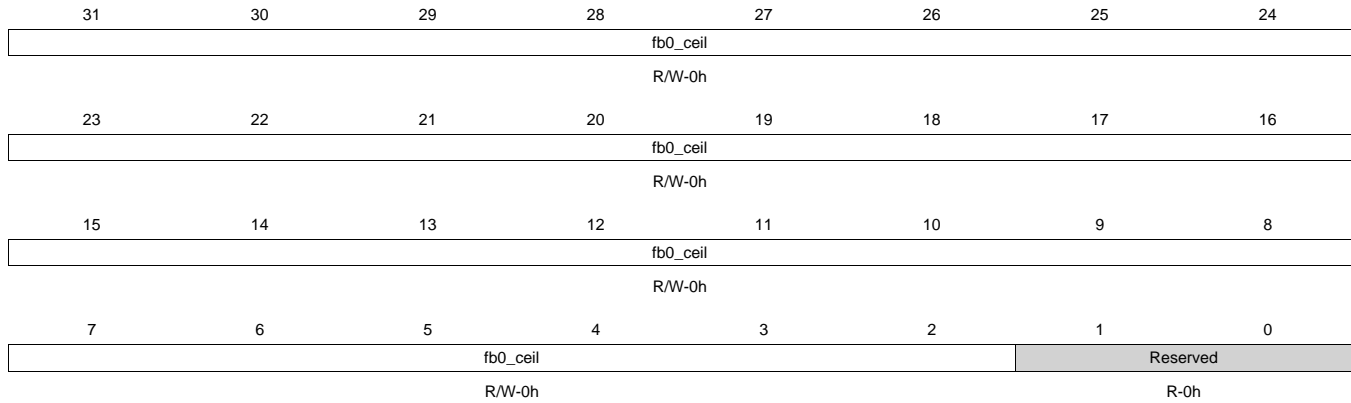

**Table 13-30. LCDDMA\_FB0\_BASE Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	fb0_base	R/W	0h	Frame Buffer 0 Base Address pointer
1-0	Reserved	R	0h	

### 13.5.18 LCDDMA\_FB0\_CEILING Register (offset = 48h) [reset = 0h]

LCDDMA\_FB0\_CEILING is shown in [Figure 13-36](#) and described in [Table 13-31](#).

**Figure 13-36. LCDDMA\_FB0\_CEILING Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

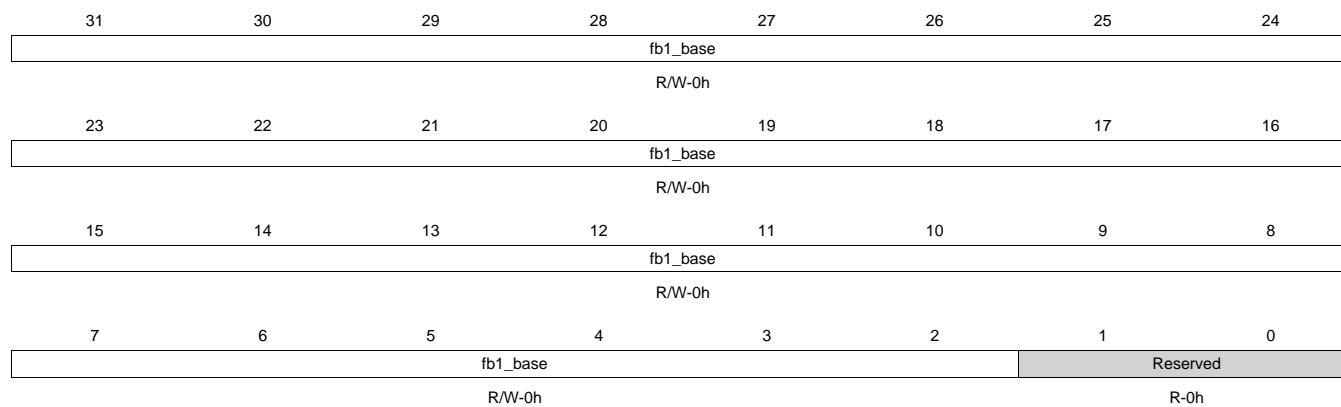

**Table 13-31. LCDDMA\_FB0\_CEILING Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	fb0_ceil	R/W	0h	Frame Buffer 0 Ceiling Address pointer
1-0	Reserved	R	0h	

### 13.5.19 LCDDMA\_FB1\_BASE Register (offset = 4Ch) [reset = 0h]

LCDDMA\_FB1\_BASE is shown in [Figure 13-37](#) and described in [Table 13-32](#).

**Figure 13-37. LCDDMA\_FB1\_BASE Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

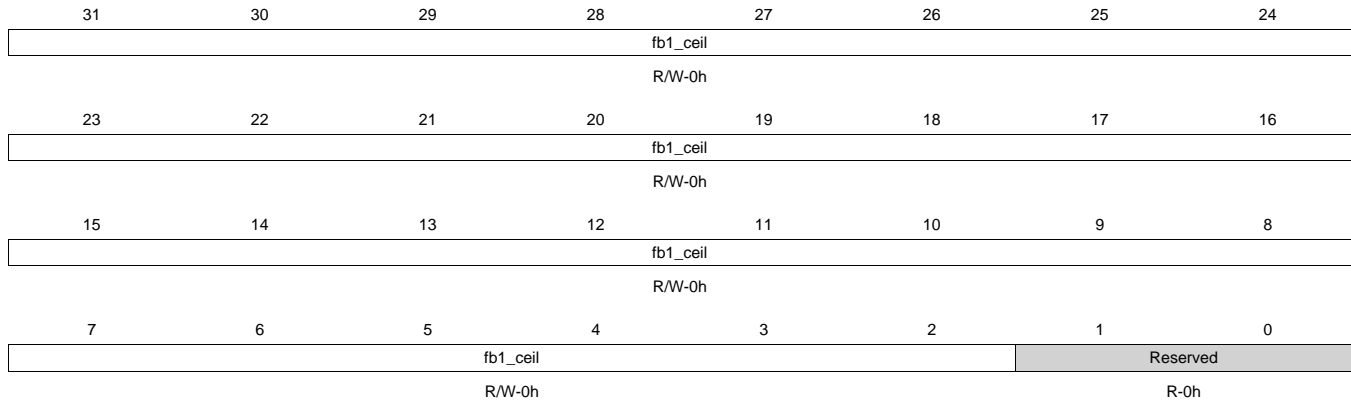

**Table 13-32. LCDDMA\_FB1\_BASE Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	fb1_base	R/W	0h	Frame Buffer 1 Base Address pointer
1-0	Reserved	R	0h	

### 13.5.20 LCDDMA\_FB1\_CEILING Register (offset = 50h) [reset = 0h]

LCDDMA\_FB1\_CEILING is shown in [Figure 13-38](#) and described in [Table 13-33](#).

**Figure 13-38. LCDDMA\_FB1\_CEILING Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

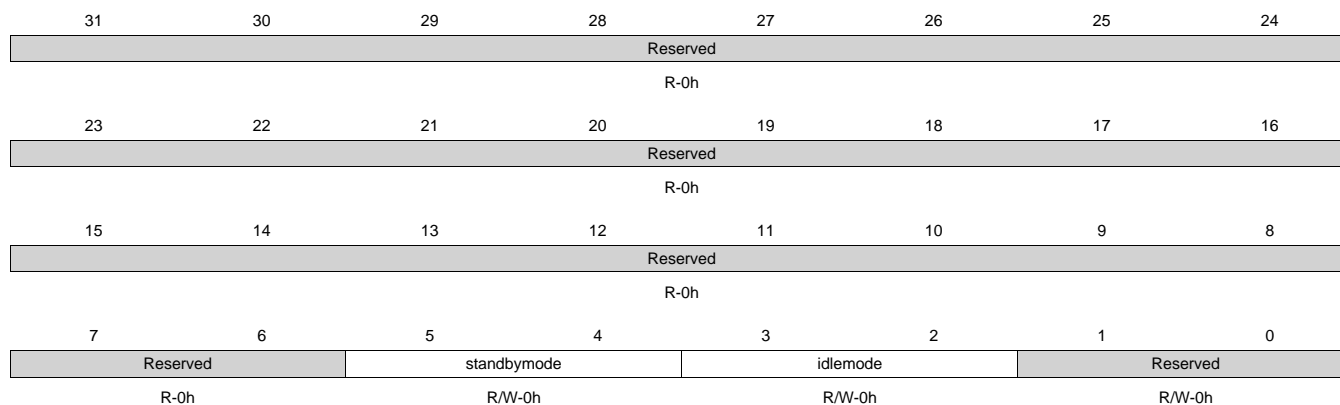

**Table 13-33. LCDDMA\_FB1\_CEILING Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	fb1_ceil	R/W	0h	Frame Buffer 1 Ceiling Address pointer
1-0	Reserved	R	0h	

### 13.5.21 SYSCONFIG Register (offset = 54h) [reset = 0h]

SYSCONFIG is shown in Figure 13-39 and described in Table 13-34.

**Figure 13-39. SYSCONFIG Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 13-34. SYSCONFIG Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-6	Reserved	R	0h	
5-4	standbymode	R/W	0h	Configuration of the local initiator state management mode By definition, initiator may generate read/write transaction as long as it is out of STANDBY state 0: Force-standby mode: local initiator is unconditionally placed in standby state Backup mode, for debug only 1: No-standby mode: local initiator is unconditionally placed out of standby state Backup mode, for debug only 2: Smart-standby mode: local initiator standby status depends on local conditions, i e the module's functional requirement from the initiator IP module shall not generate (initiator-related) wakeup events 3: Reserved
3-2	idlemode	R/W	0h	Configuration of the local target state management mode By definition, target can handle read/write transaction as long as it is out of IDLE state 0: Force-idle mode: local target's idle state follows (acknowledges) the system's idle requests unconditionally, i e regardless of the IP module's internal requirements Backup mode, for debug only 1: No-idle mode: local target never enters idle state Backup mode, for debug only 2: Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements IP module shall not generate (IRQ- or DMA-request-related) wakeup events 3: Reserved
1-0	Reserved	R/W	0h	

### 13.5.22 IRQSTATUS\_RAW Register (offset = 58h) [reset = 0h]

IRQSTATUS\_RAW is shown in [Figure 13-40](#) and described in [Table 13-35](#).

## Ethernet Subsystem

---

---

---

This chapter describes the ethernet subsystem of the device.

Topic	Page
<b>14.1 Introduction</b> .....	<b>1164</b>
<b>14.2 Integration</b> .....	<b>1166</b>
<b>14.3 Functional Description</b> .....	<b>1176</b>
<b>14.4 Software Operation</b> .....	<b>1235</b>
<b>14.5 Ethernet Subsystem Registers</b> .....	<b>1240</b>

## 14.1 Introduction

Described in the following sections is the 3-port switch (3PSW) Ethernet subsystem. The 3-port switch gigabit ethernet subsystem provides ethernet packet communication and can be configured as an ethernet switch. It provides the gigabit media independent interface (GMII), reduced gigabit media independent interface (RGMII), reduced media independent interface (RMII), the management data input output (MDIO) for physical layer device (PHY) management.

### 14.1.1 Features

The general features of the ethernet switch subsystem are:

- Two 10/100/1000 Ethernet ports with GMII, RMII and RGMII interfaces
- Wire rate switching (802.1d)
- Non Blocking switch fabric
- Flexible logical FIFO based packet buffer structure
- Four priority level QOS support (802.1p)
- CPPI 3.1 compliant DMA controllers
- Support for IEEE 1588v2 Clock Synchronization (2008 Annex D and Annex F)
  - Timing FIFO and time stamping logic inside the SS
- Device Level Ring (DLR) Support
- Address Lookup Engine
  - 1024 addresses plus VLANs
  - Wire rate lookup
  - VLAN support
  - Host controlled time-based aging
  - Spanning tree support
  - L2 address lock and L2 filtering support
  - MAC authentication (802.1x)
  - Receive or destination based Multicast and Broadcast limits
  - MAC address blocking
  - Source port locking
  - OUI host accept/deny feature
- Flow Control Support (802.3x)
- EtherStats and 802.3Stats RMON statistics gathering (shared)
- Support for external packet dropping engine
- CPGMAC\_SL transmit to CPGMAC\_SL receive Loopback mode (digital loopback) supported
- CPGMAC\_SL receive to CPGMAC\_SL transmit Loopback mode (FIFO loopback) supported
- Maximum frame size 2016 bytes (2020 with VLAN)
- 8k (2048 x 32) internal CPPI buffer descriptor memory
- MDIO module for PHY Management
- Programmable interrupt control with selected interrupt pacing
- Emulation Support.
- Programmable transmit Inter-Packet Gap (IPG)
- Reset isolation

### 14.1.2 Unsupported Features

There are 18 level interrupts from the CPGMAC module and 2 (used) level interrupts from the MDIO module. The CPSW\_3GSS includes an interrupt combiner/pacer to combine these interrupts together to produce 4 interrupt outputs (per processing core). This device does not split processing among multiple cores but allows servicing of the Core0 interrupts by the Cortex A8 or the PRU-ICSS.

The unsupported CPGMAC features in the device are shown in the following table.

**Table 14-1. Unsupported CPGMAC Features**

Feature	Reason
Multi-core split processing	Core 1 and Core 2 interrupts not connected.
GMII	Only 4 Rx/Tx data pins are pinned out for each port. The device supports MII (on GMII interface), RGMII, and RMII interfaces only
Phy link status	The MLINK inputs are not pinned out. Phy link status outputs can be connected to device GPIOs.
Internal Delay mode for RGMII	RGMII Internal Delay mode is not supported.
RMII reference clock output mode	RMII reference clock does not satisfy input requirements of RMII Ethernet PHYs.
Reset isolation	Silicon bug. For more information, see <i>AM335x ARM Cortex-A8 Microprocessors (MPUs) Silicon Errata</i> (literature number <a href="#">SPRZ360</a> ).

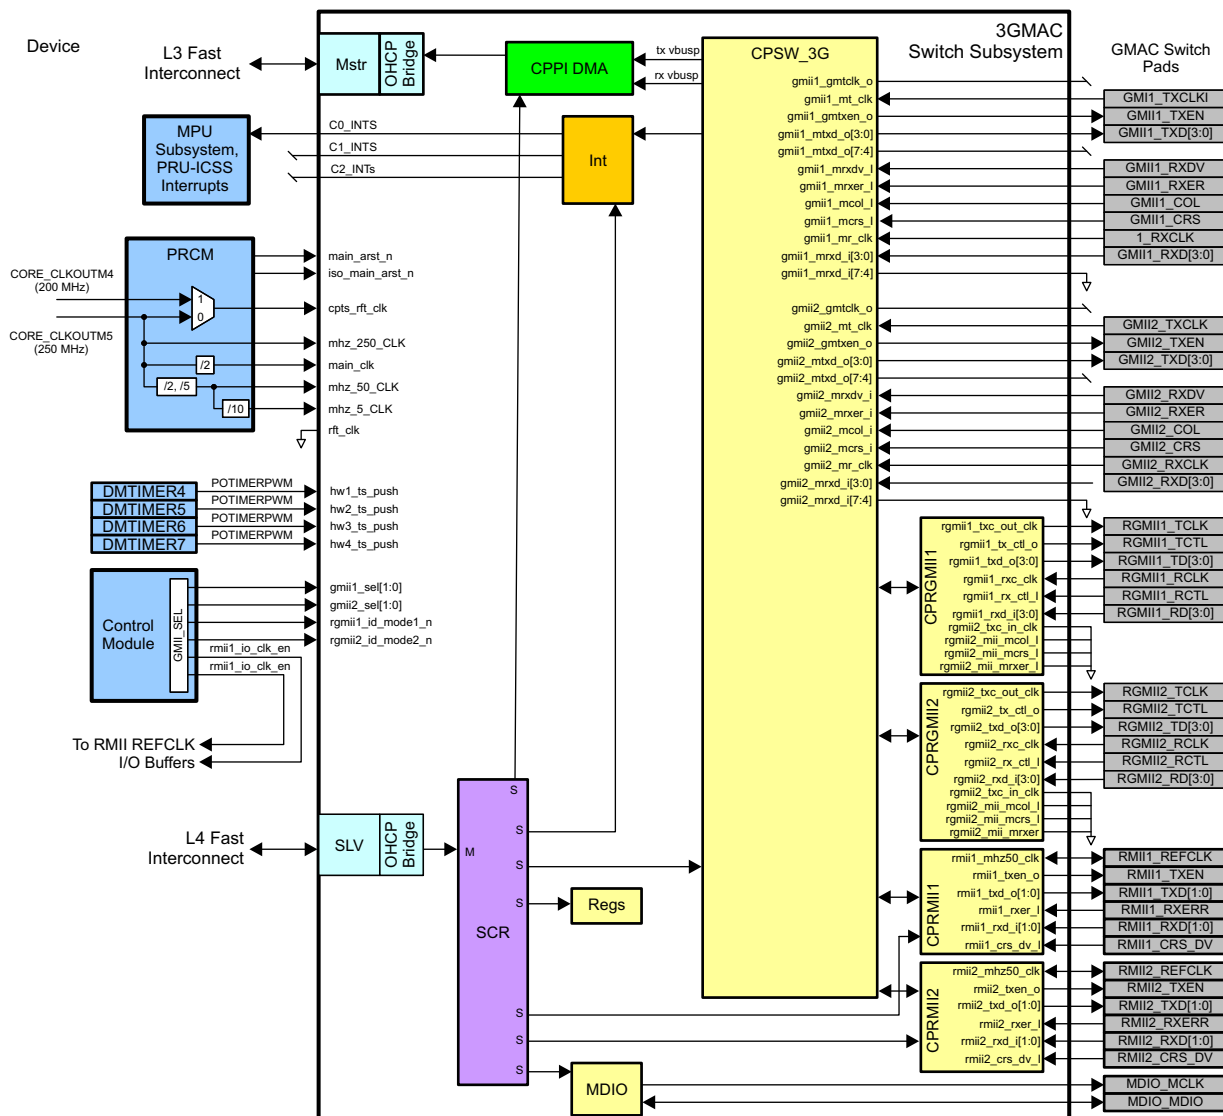

## 14.2 Integration

This device includes a single instantiation of the three-port Gigabit Ethernet Switch Subsystem (CPSW\_3GSS\_RG). The switch provides 2 external ethernet ports (ports 1 and 2) and an internal CPPI interface port (port 0) with IEEE 1588v2 and 802.1ae support. The subsystem consists of:

- One instance of the 3-port Gigabit switch CPSW-3G, which contains:
  - 2 CPGMAC\_SL 10/100/1000 ethernet port modules with GMII interface
- Two RGMII interface modules
- Two RMII interface modules
- One MDIO interface module
- One Interrupt Controller module
- Local CPPI memory of size 8K Bytes

The integration of the Ethernet Switch is shown in [Figure 14-1](#)

**Figure 14-1. Ethernet Switch Integration**

### 14.2.1 Ethernet Switch Connectivity Attributes

The general connectivity attributes for the Ethernet Switch module are shown in [Table 14-2](#).

**Table 14-2. Ethernet Switch Connectivity Attributes**

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_CPSW_125MHZ_GCLK (Main) PD_PER_CPSW_250MHZ_GCLK (MHZ_250_CLK) PD_PER_CPSW_50MHZ_GCLK (MHZ_50_CLK) PD_PER_CPSW_5MHZ_GCLK (MHZ_5_CLK) PD_PER_CPSW_CPTS_RFT_CLK (CPTS_RFT_CLK)
Reset Signals	CPSW_MAIN_ARST_N CPSW_ISO_MAIN_ARST_N
Idle/Wakeup Signals	Idle Standby
Interrupt Requests	4 Interrupts RX_THRESH (3PGSWRXTHR0) – Receive Threshold interrupt (nonpaced) RX (3PGSWRXINT0) – Receive interrupt (paced) TX (3PGSWTXINT0) – Transmit interrupt (paced) Misc (3PGSWMISC0) – Other interrupts All Ethernet Switch interrupts go to MPU Subsystem and PRU-ICSS. The Subsystem contains 3 sets of interrupts C0, C1, and C2 to allow for split core processing of packets. On this device, only the C0 version of the interrupts is used.
DMA Requests	None
Physical Address	L4 Fast slave port L3 Fast initiator port

## 14.2.2 Ethernet Switch Clock and Reset Management

The ethernet switch controller operates in its own clock domain and its initiator and target interfaces are connected to the L3/L4 through asynchronous bridges. The OCP interfaces are driven by the MAIN clock input. Additional reference clock inputs are provided for operating the various ethernet ports at different rates.

**Table 14-3. Ethernet Switch Clock Signals**

<b>Clock Signal</b>	<b>Max Freq</b>	<b>Reference / Source</b>	<b>Comments</b>
rft_clk Gigabit GMII Tx Reference clock	125 MHz	Tied low	not supported
main_clk Logic/Interface clock	125 MHz	CORE_CLKOUTM5 / 2	pd_per_cpsw_125mhz_gclk from PRCM
mhz250_clk Gigabit RGMII Reference clock	250 MHz	CORE_CLKOUTM5	pd_per_cpsw_250mhz_gclk from PRCM
mhz50_clk RMII and 100mbps RGMII Reference clock	50 MHz	CORE_CLKOUTM5 / 5	pd_per_cpsw_50mhz_gclk from PRCM
mhz5_clk 10 mbpsRGMII Reference clock	5 MHz	CORE_CLKOUTM5 / 50	pd_per_cpsw_5mhz_gclk from PRCM
cpts_rft_clk IEEE 1588v2 clock	250 MHz	CORE_CLKOUTM4 CORE_CLKOUTM5	pd_per_cpsw_cpts_rft_clk from PRCM
gmii1_mr_clk GMII Port 1 Receive clock	25 MHz	External Pin	gmii1_rxclk_in from GMII1_RCLK pad
gmii2_mr_clk GMII Port 2 Receive clock	25 MHz	External Pin	gmii2_rxclk_in from GMII2_RCLK pad
gmii1_mt_clk GMII Port 1 Transmit clock	25 MHz	External Pin	gmii1_txclk_in from GMII1_TCLK pad
gmii2_mt_clk GMII Port 2 Transmit clock	25 MHz	External Pin	gmii2_txclk_in from GMII2_TCLK pad
rgmii1_rxc_clk RGMII Port 1 Receive clock	250 MHz	External Pin	rgmii1_rclk_in from RGMII1_RCLK pad
rgmii2_rxc_clk RGMII Port 2 Receive clock	250 MHz	External Pin	rgmii2_rclk_in from RGMII2_RCLK pad
rmii1_mhz_50_clk RMII Port 1 Reference clock	50 MHz	External Pin	rmii1_refclk_in from RMII1_REFCLK pad
rmii2_mhz_50_clk RMII Port 2 Reference clock	50 MHz	External Pin	rmii2_refclk_in from RMII2_REFCLK pad

### 14.2.3 Ethernet Switch Pin List

The external signals for the Ethernet Switch module are shown in the following table.

**Table 14-4. Ethernet Switch Pin List**

Pin	Type*	Description
GMIIx_RXCLK	I	GMII/MII Receive clock
GMIIx_RXD[7:0]	I	GMII/MII Receive data
GMIIx_RXDV	I	GMII/MII Receive data valid
GMIIx_RXER	I	GMII/MII Receive error
GMIIx_COL	I	GMII/MII Collision detect
GMIIx_CRS	I	GMII/MII Carrier sense
GMIIx_TXCLK	I	GMII/MII Transmit clock
GMII_TXD[7:0]	O	GMII/MII Transmit data
GMIIx_TXEN	O	GMII/MII Transmit enable
RGMIIx_RCLK	I	RGMII Receive clock
RGMIIx_RCTL	I	RGMII Receive control
RGMIIx_RD[3:0]	I	RGMII Receive data
RGMIIx_TCLK	O	RGMII Transmit clock
RGMIIx_TCTL	O	RGMII Transmit control
RGMIIx_TD[3:0]	O	RGMII Transmit data
RMIIx_RXD[1:0]	I	RMII Receiver data
RMIIx_RXER	I	RMII Receiver error
RMIIx_CRS_DV	I	RMII Carrier sense / Data valid
RMIIx_TXEN	O	RMII Transmit enable
RMIIx_REFCLK	I/O	RMII Reference clock
RMIIx_TXD[1:0]	O	RMII Transmit data
MDIO_MCLK	O	MDIO Serial clock
MDIO_MDIO	I/O	MDIO Serial data

### 14.2.4 Ethernet Switch RMII Clocking Details

The RMII interface reference clock pin operates as an input. When used as an input, the clock is driven by the I/O pad. The operation is controlled by the GMII\_SEL[RMIIx\_IO\_CLK\_EN] fields in the Control Module, as shown in [Figure 14-2](#).

Figure 14-2. Ethernet Switch RMII Clock Detail

### 14.2.5 GMII Interface Signal Connections and Descriptions

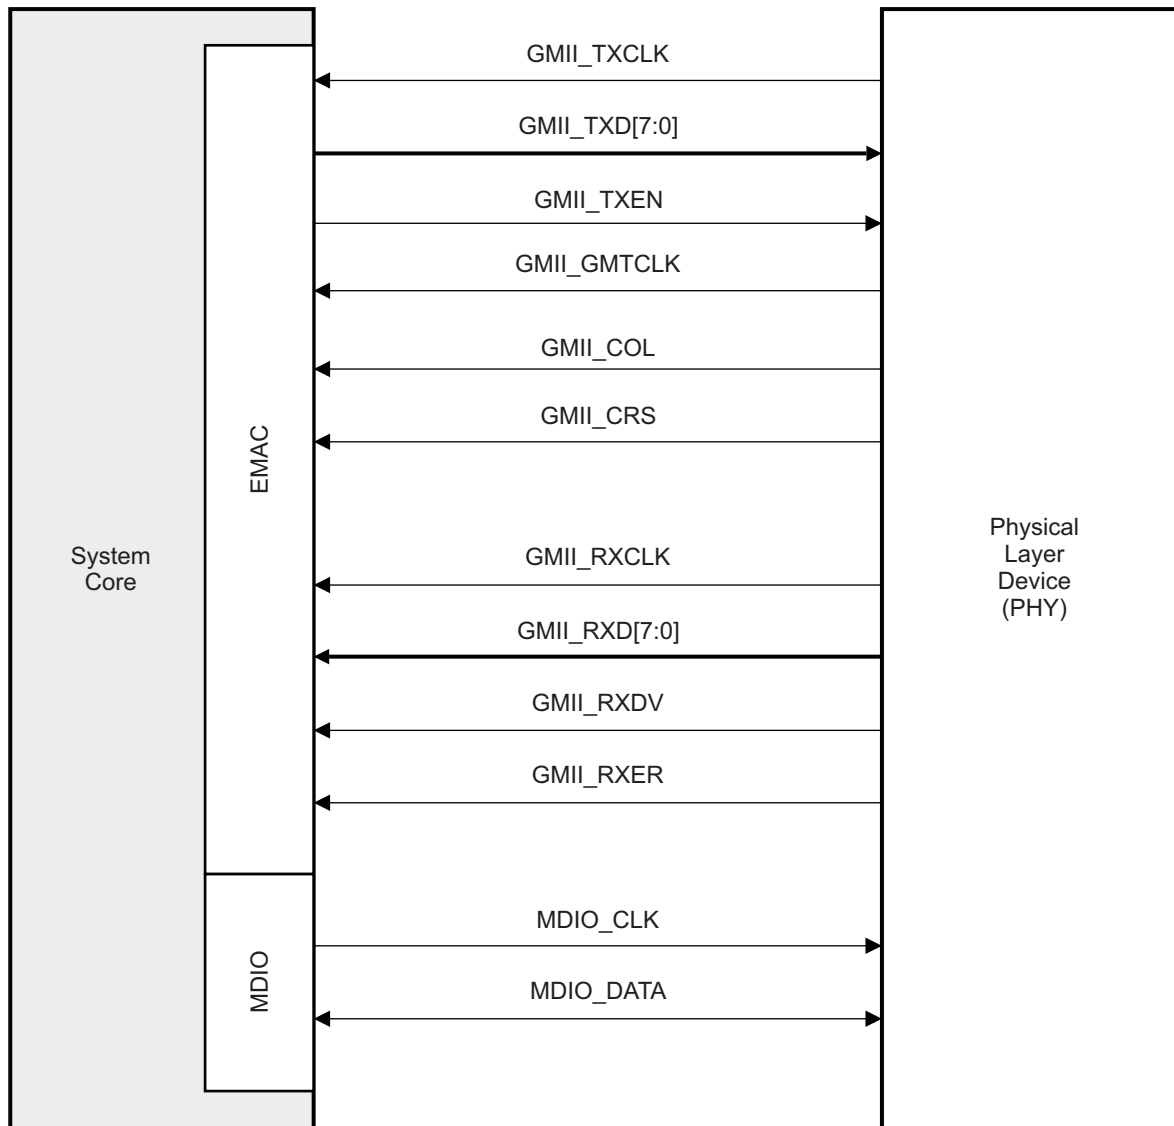

GMII Interface can operate in GIG/MII Modes.

In GIG(1000Mbps) Mode 3PSW operates only in Full duplex Mode.

In MII Mode(100/10 Mbps) 3PSW operates in Full duplex and Half Duplex.

The pin connections of the GMII Interface are shown in [Figure 14-3](#).

Figure 14-3. MII Interface Connections

The detailed description of the signals in GIG/MII Mode are explained in the following sections.

#### 14.2.5.1 GMII Interface Signal Descriptions in GIG (1000Mbps) Mode

Table 14-5. GMII Interface Signal Descriptions in GIG (1000Mbps) Mode

Signal	Type	Description
GMTCLK	O	The transmit clock is a continuous clock that provides the timing reference for transmit operations. The clock is generated by the CPSW and is 125 MHz at 1000 Mbps operation.
MtCLK	I	The transmit clock is a continuous free running clock and is generated by the PHY.
Mtxd	O	The transmit data pins are a collection of 8 data signals comprising 8 bits of data. MTXD0 is the least-significant bit (LSB). The signals are synchronized by GMTCLK and valid only when MTXEN is asserted.
Mtxen	O	The transmit enable signal indicates that the MTXD pins are generating 8bit data for use by the PHY. It is driven synchronously by GMTCLK.

**Table 14-5. GMII Interface Signal Descriptions in GIG (1000Mbps) Mode (continued)**

Signal	Type	Description
MCOL	I	In full-duplex operation, the MCOL pin is used for hardware transmit flow control. Asserting the MCOL pin will stop packet transmissions; packets in the process of being transmitted when MCOL is asserted will complete transmission. The MCOL pin should be held low if hardware transmit flow control is not used.
MCRS	I	In full-duplex operation, the MCRS pin should be held low.
MRCLK	I	The receive clock is a continuous clock that provides the timing reference for receive operations. The MRXD,MRXDV, and MRXER signals are tied to this clock.The clock is generated by the PHY and is 125 MHz at 1000Mbps of operation.
MRXD	I	The receive data pins are a collection of 8 data signals comprising 8 bits of data.MRXD0 is the least-significant bit (LSB).The signals are synchronized by MRCLK and valid only when MRXDV is asserted.
MRXDV	I	The receive data valid signal indicates that the MRXD pins are generating byte data for use by the 3PSW. It is driven synchronously to MRCLK.
MDCLK	O	Management data clock (MDIO_CLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin.
MDIO	I/O	MDIO DATA(MDIO_D). MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication,PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

**14.2.5.2**
**Table 14-6. GMII Interface Signal Descriptions in MII (100/10Mbps) Mode**

Signal	Type	Description
GMTCLK	O	The clock is generated by the CPSW and is running at 125 MHz
MtCLK	I	The transmit clock is a continuous clock that provides the timing reference for transmit operations. The MTXD and MTXEN signals are tied to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation.
Mtxd	O	MTXD[7-4] pins of MTXD data are not used.The transmit data pins are a collection of 4 data signals MTXD[3-0] comprising 4 bits of data. MTXD0 is the least-significant bit (LSB). The signals are synchronized by MTCLK and valid only when MTXEN is asserted.
Mtxen	O	The transmit enable signal indicates that the MTXD pins are generating 4bit data for use by the PHY. It is driven synchronously by MTCLK.
MCOL	I	In half-duplex operation, the MCOL pin is asserted by the PHY when it detects a collision on the network. It remains asserted while the collision condition persists.This signal is not necessarily synchronous to MTCLK nor MRCLK. In full-duplex operation, the MCOL pin is used for hardware transmit flow control. Asserting the MCOL pin will stop packet transmissions; packets in the process of being transmitted when MCOL is asserted will complete transmission. The MCOL pin should be held low if hardware transmit flow control is not used
MCRS	I	In half-duplex operation, the MCRS pin is asserted by the PHY when the network is not idle in either transmit or receive. The pin is deasserted when both transmit and receive are idle. This signal is not necessarily synchronous to MTCLK nor MRCLK. In full-duplex operation, the MCRS pin should be held low.
MRCLK	I	The receive clock is a continuous clock that provides the timing reference for receive operations. The MRXD, MRXDV, and MRXER signals are tied to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation.
MRXD	I	MRXD[7-4] bits are unused in the MII mode.The receive data pins are a collection of 4 data signals comprising 4 bits of data.MRXD0 is the least-significant bit (LSB).The signals are synchronized by MRCLK and valid only when MRXDV is asserted.

**Table 14-6. GMII Interface Signal Descriptions in MII (100/10Mbps) Mode (continued)**

Signal	Type	Description
MRXDV	I	The receive data valid signal indicates that the MRXD pins are generating nibble data for use by the 3PSW. It is driven synchronously to MRCLK.
MDCLK	O	Management data clock (MDIO_CLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin.
MDIO	I/O	MDIO DATA(MDIO_D). MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication,PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

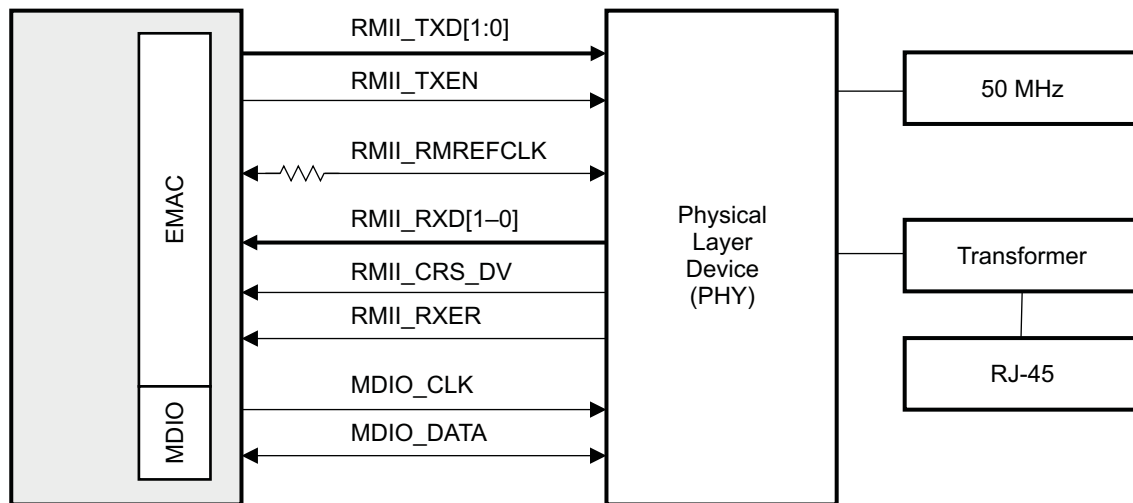

**14.2.6 RMII Signal Connections and Descriptions**

Figure 14-4 shows a device with integrated 3PSW and MDIO interfaced via a RMII connection in a typical system.

The individual CPSW and MDIO signals for the RMII interface are summarized in Table 14-7.

For more information, see either the IEEE 802.3 standard or ISO/IEC 8802-3:2000(E).

**Figure 14-4. RMII Interface Connections**

**Table 14-7. RMII Interface Signal Descriptions**

Signal	Type	Description
RMII_TXD[1-0]	O	Transmit data. The transmit data pins are a collection of 2 bits of data. RMII_TXD0 is the least-significant bit (LSB). The signals are synchronized by RMII_REFCLK and valid only when RMII_TXEN is asserted.
RMII_TXEN	O	Transmit enable. The transmit enable signal indicates that the RMII_TXD pins are generating data for use by the PHY. RMII_TXEN is synchronous to RMII_MHZ_50_CLK.
RMII_REFCLK	I	RMII reference clock. The reference clock is used to synchronize all RMII signals. RMII_REFCLK must be continuous and fixed at 50 MHz.
RMII_RXD[1-0]	I	Receive data. The receive data pins are a collection of 2 bits of data. RMII_RXD0 is the least-significant bit (LSB). The signals are synchronized by RMII_REFCLK and valid only when RM_CRS_DV is asserted and RMII_RXER is deasserted.
RMII_CRS_DV	I	Carrier sense/receive data valid. Multiplexed signal between carrier sense and receive data valid.

**Table 14-7. RMI Interface Signal Descriptions (continued)**

Signal	Type	Description
RMII_RXER	I	Receive error. The receive error signal is asserted to indicate that an error was detected in the received frame.
MDIO_CLK	O	Management data clock. The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin.
MDIO_DATA	I/O	MDIO DATA. MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_DATA signal acts as an output for all but the data bit cycles at which time it is an input for read operations.

### 14.2.7 RGMII Signal Connections and Descriptions

Figure 14-5 shows a device with integrated CPSW and MDIO interfaced via a RGMII connection in a typical system.

**Figure 14-5. RGMII Interface Connections**

**Table 14-8. RGMII Interface Signal Descriptions**

Signal	Type	Description
RGMII_TD[3-0]	O	The transmit data pins are a collection of 4 bits of data. RGMII_RD0 is the least-significant bit (LSB). The signals are valid only when RGMII_TCTL is asserted.
RGMII_TCTL	O	Transmit Control/enable .The transmit enable signal indicates that the RGMII_TD pins are generating data for use by the PHY.
RGMII_TCLK	O	The transmit reference clock will be 125Mhz, 25Mhz, or 2.5Mhz depending on speed of operation.
RGMII_RD[3-0]	I	The receive data pins are a collection of 4 bits of data. RGMII_RD is the least-significant bit (LSB). The signals are valid only when RGMII_RCTL is asserted.
RGMII_RCTL	I	The receive data valid/control signal indicates that the RGMII_RD pins are nibble data for use by the 3PSW.
RGMII_RCLK	I	The receive clock is a continuous clock that provides the timing reference for receive operations.The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation,125 MHz at 1000Mbps of operation.
MDIO_CLK	O	Management data clock. The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin.
MDIO_DATA	I/O	MDIO DATA. MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication,PHY address, register address, and data bit cycles. The MDIO_DATA pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

## 14.3 Functional Description

The 3 port switch (3PSW) Ethernet Subsystem peripheral are compliant to the IEEE Std 802.3 Specification. The 3PSW Ethernet Subsystem contains two RGMII/RMII interfaces, one CPPI 3.0 interface, Interrupt Controller, MDIO and CPSW\_3G which contains two GMII interfaces as shown in [Figure 14-6](#).

The subsystem modules are discussed in detail in the following sections.

### 14.3.1 CPSW\_3G Subsystem

#### 14.3.1.1 Interrupt Pacing

The receive and transmit pulse interrupts can be paced. The receive threshold and miscellaneous interrupts are not paced. The Interrupt pacing feature limits the number of interrupts that occur during a given period of time. For heavily loaded systems in which interrupts can occur at a very high rate (e.g. 148,800 packets per second for Ethernet), the performance benefit is significant due to minimizing the overhead associated with servicing each interrupt. Interrupt pacing increases the CPU cache hit ratio by minimizing the number of times that large interrupt service routines are moved to and from the CPU instruction cache.

Each CPU receive and transmit pulse interrupt contains an interrupt pacing sub-block (six total). Each sub-block is disabled by default allowing the selected interrupt inputs to pass through unaffected. The interrupt pacing module counts the number of interrupts that occur over a 1ms interval of time. At the end of each 1ms interval, the current number of interrupts is compared with a target number of interrupts (specified by the associated maximum number of interrupts register).

Based on the results of the comparison, the length of time during which interrupts are blocked is dynamically adjusted. The 1ms interval is derived from a 4us pulse that is created from a prescale counter whose value is set in the `int_prescale` value in the `Int_Control` register. The `int_prescale` value should be written with the number of VBUSP\_CLK periods in 4us. The pacing timer determines the interval during which interrupts are blocked and decrements every 4us. It is reloaded each time a zero count is reached. The value loaded into the pacing timer is calculated by hardware every 1ms according to the following algorithm:

```

if (intr_count > 2*intr_max)
  pace_timer = 255;
else if (intr_count > 1.5*intr_max)
  pace_timer = last_pace_timer*2 + 1;
else if (intr_count > 1.0*intr_max)
  pace_timer = last_pace_timer + 1;
else if (intr_count > 0.5*intr_max)
  pace_timer = last_pace_timer - 1;
else if (intr_count != 0)
  pace_timer = last_pace_timer/2;
else
  pace_timer = 0;

```

If the rate of interrupt inputs is much less than the target interrupt rate specified in the associated maximum interrupts register, then the interrupt is not blocked. If the interrupt rate is greater than the target rate, the interrupt will be “paced” at the rate specified in the interrupt maximum register. The interrupt maximum register should be written with a value between 2 and 63 inclusive indicating the target number of interrupts per milli-second.

#### 14.3.1.2 Reset Isolation

Reset isolation for the Ethernet switch on Device is that the switch function of the ethernet IP remains active even in case of all device resets except for POR pin reset and ICEPICK COLD reset. Packet traffic to/from the 3PSW host will be flushed/dropped, but the ethernet switch will remain operational for all traffic between external devices on the switch even though the device is under-going a device reset. Pin mux configuration for ethernet related IO and reference clocks needed by the Ethernet switch IP to be active is controlled by a protected control module bit. If reset isolation is enabled, then only a POR pin or ICEPICK COLD reset event should fully reset the Ethernet switch IP including the actual switch and also the reference clocks and pin mux control specifically associated with the Ethernet IP.

#### 14.3.1.2.1 Modes of Operation

The device has two modes of operation concerning the reset of the 3PSW Ethernet switch.

The mode is controlled by the ISO\_CONTROL bit in **RESET\_ISO** register of the **device control module**. This bit should default to '0'. Writes to the ISO\_CONTROL bit must be supervisor mode writes.

Mode 1: ISO\_CONTROL=0 (reset isolation disabled)

- This mode is selected when ISO\_CONTROL bit of control module is = 0. This should be the default state of the bit after control module reset.
- Upon any device level resets, the entire CPSW\_3GSS\_R IP, L3/L4, control module (including all pin mux control and the ISO\_CONTROL bit) is immediately reset.

Mode 2: ISO\_CONTROL=1 (reset isolation enabled)

- This mode is selected when ISO\_CONTROL bit of control module is = 1.
- Upon any device reset source other than POR pin or ICEPICK cold (so this includes SW global cold, any watchdog reset, warm RESETn pin, ICEPICK warm, SW global warm), the following should be true:
  - The CPSW\_3GSS\_R is put into 'isolate' mode and non-switch related portions of the IP are reset.
  - The 50-MHz and 125-MHz reference clocks to the 3PSW Ethernet Subsystem remains active throughout the entire reset condition.
  - The control for pin multiplexing for all of the signals should maintain their current configuration throughout the entire reset condition.
  - The reset isolated logic inside 3PSW Ethernet Subsystem IP which maintains the switch functionality
  -
- Upon any cold reset sources, the entire 3PSW Ethernet Subsystem, control module (including all pin mux control and the ISO\_CONTROL bit itself) is reset.

### 14.3.1.3 Interrupts

The 3 Port Switch Ethernet Subsystem generates four interrupt events.

#### 14.3.1.3.1 Receive Packet Completion Pulse Interrupt (RX\_PULSE)

The RX\_PULSE interrupt is a paced pulse interrupt selected from the 3PSW RX\_PEND [7:0] interrupts. The receive DMA controller has eight channels with each channel having a corresponding (RX\_PEND[7:0]).

The following steps will enable the receive packet completion interrupt.

- Enable the required channel interrupts of the DMA engine by setting 1 to the appropriate bit in the RX\_INTMASK\_SET register.
- The receive completion interrupt(s) to be routed to RX\_PULSE is selected by setting one or more bits in the receive interrupt enable register Cn\_RX\_EN. The masked interrupt status can be read in the Receive Interrupt Masked Interrupt Status (Cn\_RX\_STAT) register.

When the 3PSW completes a packet reception, the subsystem issues an interrupt to the CPU by writing the packet's last buffer descriptor address to the appropriate channel queue's receive completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon interrupt reception, the CPU processes one or more packets from the buffer chain and then acknowledges one or more interrupt(s) by writing the address of the last buffer descriptor processed to the queue's associated receive completion pointer (RXn\_CP) in the receive DMA state RAM.

Upon reception of an interrupt, software should perform the following:

- Read the RX\_STAT register to determine which channel(s) caused the interrupt.
- Process received packets for the interrupting channel(s).
- Write the 3PSW completion pointer(s) (RXn\_CP). The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the subsystem (address of last buffer descriptor used by the subsystem). If the two values are not equal (which means that the 3PSW has received more packets than the CPU has processed), the receive packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the system has received), the pending interrupt is de-asserted. The value that the 3PSW is expecting is found by reading the receive channeln completion pointer register (RXn\_CP).
- Write the value 1h to the CPDMA\_EOI\_VECTOR register.

To disable the interrupt:

- The eight channel interrupts may be individually disabled by writing to 1 the appropriate bit in the RX\_INTMASK\_CLEAR
- The receive completion pulse interrupt could be disabled by clearing to 0 all the bits of the RX\_EN.

The software could still poll for the RX\_INTSTAT\_RAW and RX\_INTSTAT\_MASKED registers if the corresponding interrupts are enabled.

#### 14.3.1.3.2 Transmit Packet Completion Pulse Interrupt (TX\_PULSE)

The TX\_PULSE interrupt is a paced pulse interrupt selected from the 3PSW TX\_PEND [7:0] interrupts. The transmit DMA controller has eight channels with each channel having a corresponding (TX\_PEND[7:0]).

To enable the transmit packet completion interrupt:

- Enable the required channel interrupts of the DMA engine by setting 1 to the appropriate bit in the TX\_INTMASK\_SET register.
- The transmit completion interrupt(s) to be routed to TX\_PULSE is selected by setting one or more bits in the transmit interrupt enable register Cn\_TX\_EN. The masked interrupt status can be read in the Transmit Interrupt Masked Interrupt Status (Cn\_TX\_STAT) register.

When the 3PSW completes the transmission of a packet, the 3PSW subsystem issues an interrupt to the CPU by writing the packet's last buffer descriptor address to the appropriate channel queue's transmit completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon receiving an interrupt, software should perform the following:

- Read the TX\_STAT register to determine which channel(s) caused the interrupt
- Process received packets for the interrupting channel(s).
- Write the 3PSW completion pointer(s) (TX<sub>n</sub>\_CP). The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the 3PSW (address of last buffer descriptor used by the 3PSW). If the two values are not equal (which means that the 3PSW has transmitted more packets than the CPU has processed), the transmit packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the subsystem has transferred), the pending interrupt is cleared. The value that the 3PSW is expecting is found by reading the transmit channel<sub>n</sub> completion pointer register (TX<sub>n</sub>\_CP).
- Write the 2h to the CPDMA\_EOI\_VECTOR register.

To disable the interrupt:

- The eight channel interrupts may be individually disabled by writing to 1 the appropriate bit in the TX\_INTMASK\_CLEAR.
- The receive completion pulse interrupt could be disabled by clearing to 0 all the bits of the TX\_EN. The software could still poll for the TX\_INTSTAT\_RAW and TX\_INTSTAT\_MASKED registers if the corresponding interrupts are enabled.

#### 14.3.1.3.3 Receive Threshold Pulse Interrupt (RX\_THRESH\_PULSE)

The RX\_THRESH\_PULSE interrupt is an immediate (non-paced) pulse interrupt selected from the CPSW\_3G RX\_THRESH\_PEND[7:0] interrupts. The receive DMA controller has eight channels with each channel having a corresponding threshold pulse interrupt (RX\_THRESH\_PEND [7:0]).

To enable the receive threshold pulse Interrupt:

- Enable the required channel interrupts of the DMA engine by setting 1 to the appropriate bit in the RX\_INTMASK\_SET register.
- The receive threshold interrupt(s) to be routed to RX\_THRESH\_PULSE is selected by setting one or more bits in the receive threshold interrupt enable register RX\_THRESH\_EN. The masked interrupt status can be read in the Receive Threshold Masked Interrupt Status (C<sub>n</sub>\_RX\_THRESH\_STAT) register.

The RX\_THRESH\_PULSE is asserted when enabled when the channel's associated free buffer count RX<sub>n</sub>\_FREEBUFFER is less than or equal to the corresponding RX<sub>n</sub>\_PENDTHRESH register.

Upon receiving an interrupt, software should perform the following:

- Read the C<sub>n</sub>\_RX\_THRESH\_STAT bit address location to determine which channel(s) caused the interrupt.
- Process the received packets in order to add more buffers to any channel that is below the threshold value.
- Write the CPSW\_3G completion pointer(s).
- Write the value 0h to the CPDMA\_EOI\_VECTOR register.

The threshold pulse interrupt is an immediate interrupt intended to indicate that software should immediately process packets to preclude an overrun condition from occurring for the particular channels.

To disable the interrupt:

- The eight channel receive threshold interrupts may be individually disabled by writing to 1 the appropriate bit in the RX\_INTMASK\_CLEAR register.
- The receive threshold pulse interrupt could be disabled by clearing to Zero the corresponding bits of the RX\_THRESH\_EN. The software could still poll for the RX\_INTSTAT\_RAW and INTSTAT\_MASKED registers if the corresponding interrupts are enabled.

#### 14.3.1.3.4 **Miscellaneous Pulse Interrupt (MISC\_PULSE)**

The MISC\_PULSE interrupt is an immediate, non-paced, pulse interrupt selected from the miscellaneous interrupts (EVNT\_PEND, STAT\_PEND, HOST\_PEND, MDIO\_LINKINT, MDIO\_USERINT). The miscellaneous interrupt(s) is selected by setting one or more bits in the *Cn\_MISC\_EN[4:0]* register. The masked interrupt status can be read in the *Cn\_MISC\_STAT[4:0]* register. Upon reception of an interrupt, software should perform the following:

- Read the *Misc\_Stat[4:0]* register to determine which caused the interrupt.
- Process the interrupt.
- Write the appropriate value (0x3) to the *CPDMA\_EOI\_VECTOR* register.
- Write a 1 to the appropriate bit in the *MDIOLINKINTRAW* register.

##### 14.3.1.3.4.1 **EVNT\_PEND (CPTS\_PEND) Interrupt**

See [Section 14.3.7](#), *Common Platform Time Sync (CPTS)*, for information on the time sync event interrupt.

##### 14.3.1.3.4.2 **Statistics Interrupt**

The statistics level interrupt (STAT\_PEND) will be asserted if enabled when any statistics value is greater than or equal to 0x80000000. The statistics interrupt is cleared by writing to decrement all statistics values greater than 0x80000000 (such that their new values are less than 0x80000000). The statistics interrupt is enabled by setting to one the appropriate bit in the *INTMASK\_SET* register in the CPDMA submodule.

The statistics interrupt is disabled by writing one to the appropriate bit in the *INTMASK\_CLEAR* register. The raw and masked statistics interrupt status may be read by reading the *TX\_IntStat\_Raw* and *TX\_IntStat\_Masked* registers, respectively

##### 14.3.1.3.4.3 **Host Error Interrupt**

The host error interrupt (HOST\_PEND) will be asserted if enabled when a host error is detected during transmit or receive CPDMA transactions. The host error interrupt is intended for software debug, and is cleared by a warm reset or a system reset. The raw and masked statistics interrupt status can be read by reading the *TX\_INTSTAT\_RAW* and *TXINTSTAT\_MASKED* registers, respectively.

The following list shows the transmit host error conditions:

- SOP error
- OWNERSHIP bit not set in SOP buffer
- next buffer descriptor pointer without EOP set to 0
- buffer pointer set to 0
- buffer length set to 0
- packet length error

The receive host error conditions are show in the following list:

- Ownership bit not set in input buffer.
- Zero buffer pointer.
- Zero buffer Length on non-SOP descriptor.
- SOP buffer length not greater than offset.

The host error interrupt is disabled by clearing to 0 the appropriate bit in the *CPDMA\_INTMASK\_CLEAR* register.

#### 14.3.1.3.4.4 MDIO Interrupts

MDIO\_LINKINT is set if there is a change in the link state of the PHY corresponding to the address in the PHYADDRMON field of the MDIOUSERPHYSEL $n$  register and the corresponding LINKINTENB bit is set. The MDIO\_LINKINT event is also captured in the MDIOLINKINTMASKED register. When the GO bit in the MDIOUSERACCESS $n$  registers transitions from 1 to 0, indicating the completion of a user access, and the corresponding USERINTMASKSET bit in the MDIOUSERINTMASKSET register is set, the MDIO\_USERINT signal is asserted 1. The MDIO\_USERINT event is also captured in the MDIOUSERINTMASKED register.

To enable the miscellaneous pulse interrupt:

The miscellaneous interrupt(s) is selected by setting one or more bits in the miscellaneous interrupt enable register (MISC\_EN).

- The Statistics interrupt is enabled by setting to 1 the STAT\_INT\_MASK bit in the DMA\_INTMASK\_SET register.
- The HOST\_PEND is enabled by setting to 1 the HOST\_ERR\_INT\_MASK in the DMA\_INTMASK\_SET register.

Upon receiving of an interrupt, software should perform the following:

- Read the C $n$ \_MISC\_STAT register to determine the source of the interrupt.
- Process the interrupt.
- Write the value 3h to the CPDMA\_EOI\_VECTOR register.

#### 14.3.1.4 Embedded Memories

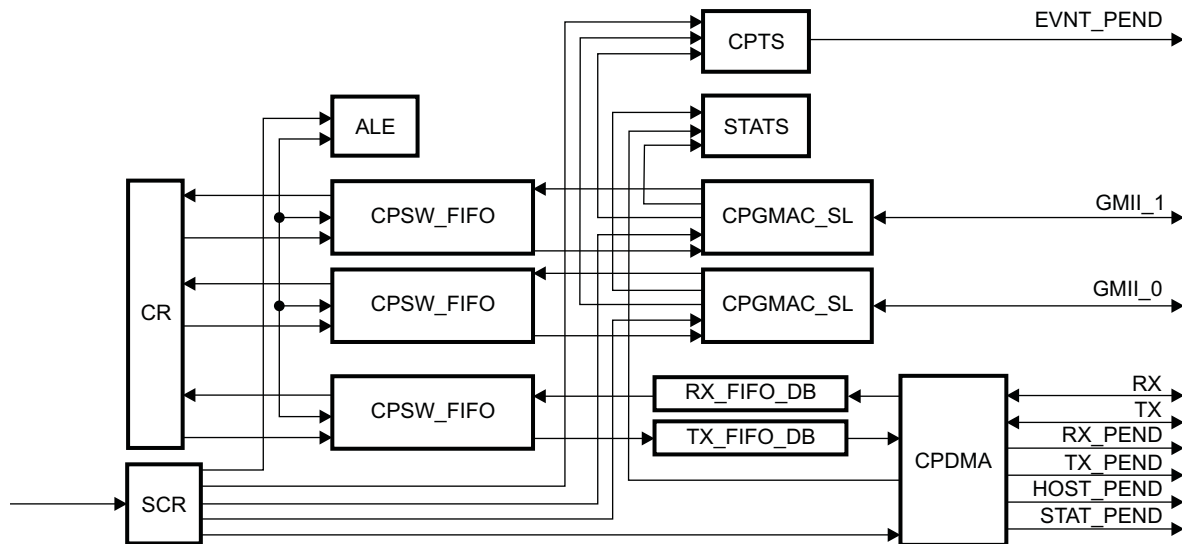

Memory Type Description	Number of Instances
Single port 2560 by 64 RAM	3 (Packet FIFOs)
Single port 64-word by 1152-bit RAM	1 (ALE)
Single port 2048-word by 32-bit RAM	1 (CPPI)

### 14.3.2 CPSW\_3G

The CPSW\_3G GMII interfaces are compliant to the IEEE Std 802.3 Specification.

The CPSW\_3G contains two CPGMAC\_SL interfaces (ports 1 and 2), one CPPI 3.0 interface Host Port (port 0), Common Platform Time Sync (CPTS), ALE Engine and CPDMA.

The top level block diagram of CPSW\_3G is shown below:

**Figure 14-6. CPSW\_3G Block Diagram**

#### 14.3.2.1 Media Independent Interface (GMII)

The CPSW\_3G contains two CPGMAC\_SL submodules. Each CPGMAC\_SL has a single GMII interface. The CPGMAC\_SL submodules are ports 1 and 2. For more details, see [Section 14.3.3, Ethernet Mac Sliver \(CPGMAC\\_SL\)](#).

#### 14.3.2.2 IEEE 1588v2 Clock Synchronization Support

The CPSW\_3G supports IEEE 1588v2 clock synchronization. Ethernet GMII Transmit (egress) and receive (ingress) time sync operation are also supported.

##### 14.3.2.2.1 IEEE 1588v2 Receive Packet Operation

There are two CPSW\_3G receive time sync interfaces for each ethernet port. The first is the TS\_RX\_MII interface and the second is the TS\_RX\_DEC interface. Both interfaces are generated in the switch and are input to the CPTS module. There are register bits in the CPSW\_3G that control time sync operations in addition to the registers in the CPTS module. The `pX_ts_rx_en` bit in the switch `Px_Control` register must be set for receive time sync operation to be enabled (TS\_RX\_MII).

The TS\_RX\_MII interface issues a record signal (`pX_ts_rx_mii_rec`) along with a handle (`pX_ts_rx_mii_hndl[3:0]`) to the CPTS controller for each packet that is received. The record signal is a single clock pulse indicating that a receive packet has been detected at the associated port MII interface.

The handle value is incremented with each packet and rolls over to zero after 15. There are 16 possible handle values so there can be a maximum of 16 packets “in flight” from the TS\_RX\_MII to the TS\_RX\_DEC block (through the CPGMAC\_SL) at any given time. A handle value is reused (not incremented) for any received packet that is shorter than about 31 octets (including preamble). Handle reuse on short packets prevents any possible overrun condition if multiple fragments are consecutively received.

The TS\_RX\_MII logic is in the receive wireside clock domain. There is no decode logic in the TS\_RX\_MII to determine if the packet is a time sync event packet or not. Each received packet generates a record signal and new handle. The handle is sent to the CPTS controller with the record pulse and the handle is also sent to the TS\_RX\_DEC block along with the packet. The packet decode is performed in the TS\_RX\_DEC block. The decode function is separated from the record function because in some systems the incoming packet can be encrypted. The decode function would be after packet decryption in those systems.

The TS\_RX\_DEC function decodes each received packet and determines if the packet meets the time sync event packet criteria. If the packet is determined to be a time sync event packet, then the time sync event packet is signaled to the CPTS controller via the TS\_RX\_DEC interface (pX\_ts\_rx\_dec\_evt, pX\_ts\_rx\_dec\_hdl[3:0], pX\_ts\_rx\_dec\_msg\_type, pX\_ts\_rx\_dec\_seq\_id). The event signal is a single clock pulse indicating that the packet matched the time sync event packet criteria and that the associated packet handle, message type, and sequence ID are valid. No indication is given for received packets that do not meet the time sync event criteria. The 16-bit sequence ID is found in the time sync event packet at the sequence ID offset into the PTP message header (pX\_ts\_seq\_id\_offset). A packet is determined to be a receive event packet under the following conditions:

#### 14.3.2.2.1.1 Annex F

1. Receive time sync is enabled (pX\_ts\_rx\_en is set in the switch Px\_Control register).
2. One of the following sequences is true:
  - Where the first packet ltype matches:
    - ts\_ltype1 and pX\_ts\_ltype1\_en is set
    - ts\_ltype2 and pX\_ts\_ltype2\_en is set
    - vlan\_ltype1 and pX\_vlan\_ltype1\_en is set and the second packet ltype matches ts\_ltype1 and pX\_ts\_ltype1\_en is set
    - vlan\_ltype1 and pX\_vlan\_ltype1\_en is set and the second packet ltype matches ts\_ltype2 and pX\_ts\_ltype2\_en is set
    - vlan\_ltype2 and pX\_vlan\_ltype2\_en is set and the second packet ltype matches ts\_ltype1 and pX\_ts\_ltype1\_en is set
    - vlan\_ltype2 and pX\_vlan\_ltype2\_en is set and the second packet ltype matches ts\_ltype2 and pX\_ts\_ltype2\_en is set
    - vlan\_ltype1 and pX\_vlan\_ltype1\_en is set and the second packet ltype matches vlan\_ltype2 and pX\_vlan\_ltype2\_en is set and the third packet ltype matches ts\_ltype1 and pX\_ts\_ltype1\_en is set
    - vlan\_ltype1 and pX\_vlan\_ltype1\_en is set and the second packet ltype matches vlan\_ltype2 and pX\_vlan\_ltype2\_en is set and the third packet ltype matches ts\_ltype2 and pX\_ts\_ltype2\_en is set
3. The PTP message begins in the byte after the LTYPE.
4. The packet message type is enabled in the pX\_ts\_msg\_type\_en field in the Px\_TS\_SEQ\_MTYPE register.
5. The packet was received without error (not long/short/mac\_ctl/crc/code/align).
6. The ALE determined that the packet is to be sent only to the host (port 0).

#### 14.3.2.2.1.2 Annex D

1. Receive time sync is enabled (pX\_ts\_rx\_en is set in the switch Px\_Control register).
2. One of the following sequences is true:
  - Where the first packet ltype matches:
    - 0x0800 and pX\_ts\_annex\_d\_en is set
    - vlan\_ltype1 and pX\_vlan\_ltype1\_en is set and the second packet ltype matches 0x0800 and pX\_ts\_annex\_d\_en is set
    - vlan\_ltype2 and pX\_vlan\_ltype2\_en is set and the second packet ltype matches 0x0800 and pX\_ts\_annex\_d\_en is set
    - vlan\_ltype1 and pX\_vlan\_ltype1\_en is set and the second packet ltype matches vlan\_ltype2 and pX\_vlan\_ltype2\_en is set and the third packet ltype matches 0x0800 and pX\_ts\_annex\_d\_en is set
3. Byte 14 (the byte after the LTYPE) contains 0x45 (IP\_VERSION).
 

**Note:** The byte numbering assumes that there are no vlans. The byte number is intended to show the relative order of the bytes.
4. Byte 22 contains 0x00 if the pX\_ts\_ttl\_nonzero bit in the switch Px\_Control register is zero or byte 22 contains any value if pX\_ts\_ttl\_nonzero is set. Byte 22 is the time to live field.

5. Byte 23 contains 0x11 (UDP Fixed).
6. Byte 30 contains decimal 224 (0xe0).
7. Byte 31 contains 0x00.
8. Byte 32 contains 0x01.
9. Byte 33 contains one of the following:
  - Decimal 129 and the pX\_ts\_129 bit in the switch Px\_Control register is set
  - Decimal 130 and the pX\_ts\_130 bit in the switch Px\_Control register is set
  - Decimal 131 and the pX\_ts\_131 bit in the switch Px\_Control register is set
  - Decimal 129 and the pX\_ts\_132 bit in the switch Px\_Control register is set
10. Bytes 36 and 37 contain one of the following:
  - Decimal 0x01 and 0x3f respectively and the pX\_ts\_319 bit in the switch Px\_Control register is set.
  - Decimal 0x01 and 0x40 respectively and the pX\_ts\_320 bit in the switch Px\_Control register is set.
11. The PTP message begins in byte 42.
12. The packet message type is enabled in the pX\_ts\_msg\_type\_en field in Px\_Control.
13. The packet was received without error (not long/short/mac\_ctl/crc/code/align).
14. The ALE determined that the packet is to be sent only to the host (port 0).

#### 14.3.2.2.2 IEEE 1588v2 Transmit Packet Operation

There are two CPSW\_3G transmit time sync interfaces for each ethernet port. The first is the TS\_TX\_DEC interface and the second is the TS\_TX\_MII interface. Both interfaces are generated in the switch and are input to the CPTS module. The pX\_ts\_tx\_en bit in the Px\_Control register must be set for transmit time sync operation to be enabled.

The TS\_TX\_DEC function decodes each packet to be transmitted and determines if the packet meets the time sync event packet criteria. If the packet is determined to be a time sync event packet, then the time sync event is signaled to the CPTS controller via the TS\_TX\_DEC interface (pX\_ts\_tx\_dec\_evt, pX\_ts\_tx\_dec\_hdl[3:0], pX\_ts\_tx\_dec\_msg\_type, pX\_ts\_tx\_dec\_seq\_id). The event signal is a single clock pulse indicating that the packet matched the time sync event packet criteria and that the associated packet handle, message type, and sequence ID are valid.

The 16-bit sequence ID is found in the time sync event packet at the sequence ID offset into the message header (pX\_ts\_seq\_id\_offset). No indication is given for transmit packets that do not meet the time sync event criteria. The time sync event packet handle is also passed along with the packet to the TS\_TX\_MII with an indication that the packet is a time sync event packet. Unlike receive, only transmit event packets increment the handle value. The decode function is separated from the record function because some systems may encrypt the packet. The encryption is after the decode function on transmit (egress). A packet is determined to be a transmit event packet if the following is met:

##### 14.3.2.2.2.1 Annex F

1. Transmit time sync is enabled (pX\_ts\_tx\_en is set in the switch Px\_Control register).
2. One of the following sequences is true:
  - The first packet ltype matches ts\_ltype1 and pX\_ts\_ltype1\_en is set
  - The first packet ltype matches ts\_ltype2 and pX\_ts\_ltype2\_en is set
  - The first packet ltype matches vlan\_ltype1 and pX\_vlan\_ltype1\_en is set and the second packet matches ts\_ltype1 and pX\_ts\_ltype1\_en is set
  - The first packet ltype matches vlan\_ltype1 and pX\_vlan\_ltype1\_en is set and the second packet ltype matches ts\_ltype2 and pX\_ts\_ltype2\_en is set
  - The first packet ltype matches vlan\_ltype2 and pX\_vlan\_ltype2\_en is set and the second packet ltype matches ts\_ltype1 and pX\_ts\_ltype1\_en is set
  - The first packet ltype matches vlan\_ltype2 and pX\_vlan\_ltype2\_en is set and the second packet

- ltype matches ts\_ltype2 and pX\_ts\_ltype2\_en is set
- The first packet ltype matches vlan\_ltype1 and pX\_vlan\_ltype1\_en is set and the second packet ltype matches vlan\_ltype2 and pX\_vlan\_ltype2\_en is set and the third packet ltype matches ts\_ltype1 and pX\_ts\_ltype1\_en is set
  - The first packet ltype matches vlan\_ltype1 and pX\_vlan\_ltype1\_en is set and the second packet ltype matches vlan\_ltype2 and pX\_vlan\_ltype2\_en is set and the third packet ltype matches ts\_ltype2 and pX\_ts\_ltype2\_en is set
3. The packet message type is enabled in pX\_ts\_msg\_type\_en.
  4. The packet was received by the host (port 0).

#### 14.3.2.2.2 Annex D

1. Transmit time sync is enabled (pX\_ts\_tx\_en is set in the switch Px\_Control register).
2. One of the following sequences is true:
  - The first packet ltype matches 0x0800 and pX\_ts\_annex\_d\_en is set
  - The first packet ltype matches vlan\_ltype1 and pX\_vlan\_ltype1\_en is set and the second packet ltype matches 0x0800 and pX\_ts\_annex\_d\_en is set
  - The first packet ltype matches vlan\_ltype2 and pX\_vlan\_ltype2\_en is set and the second packet ltype matches 0x0800 and pX\_ts\_annex\_d\_en is set
  - The first packet ltype matches vlan\_ltype1 and pX\_vlan\_ltype1\_en is set and the second packet ltype matches vlan\_ltype2 and pX\_vlan\_ltype2\_en is set and the third packet ltype matches 0x0800 and pX\_ts\_annex\_d\_en is set
3. Byte 14 (the byte after the LTYPE) contains 0x45 (IP\_VERSION).
 

**Note:** The byte numbering assumes that there are no vlans. The byte number is intended to show the relative order of the bytes. If VLAN(s) are present, then the byte numbers push down.
4. Byte 22 contains 0x00 if the pX\_ts\_ttl\_nonzero bit in the switch Px\_Control register is zero or byte 22 contains any value if pX\_ts\_ttl\_nonzero is set. Byte 22 is the time to live field.
5. Byte 23 contains 0x11 (UDP Fixed).
6. Byte 30 contains decimal 224 (0xe0)
7. Byte 31 contains 0x00
8. Byte 32 contains 0x01
9. Byte 33 contains one of the following:
  - Decimal 129 and the pX\_ts\_129 bit in the switch Px\_Control register is set
  - Decimal 130 and the pX\_ts\_130 bit in the switch Px\_Control register is set
  - Decimal 131 and the pX\_ts\_131 bit in the switch Px\_Control register is set
  - Decimal 132 and the pX\_ts\_132 bit in the switch Px\_Control register is set
10. Bytes 36 and 37 contain either of the following:
  - Decimal 1 (hex 0x01) and decimal 63 (hex 0x3f) respectively and the pX\_ts\_319 bit in the switch Px\_Control register is set
  - Decimal 1 (hex 0x01) and decimal 64 (hex 0x40) respectively and the pX\_ts\_320 bit in the switch Px\_Control register is set
11. The PTP message begins in byte 42 (this is offset 0).
12. The packet message type is enabled in pX\_ts\_msg\_type\_en.
13. The packet was received by the host (port 0).

The TS\_TX\_MII interface issues a single clock record signal (pX\_ts\_tx\_mii\_rec) at the beginning of each transmitted packet. If the packet is a time sync event packet then a single clock event signal (pX\_ts\_tx\_mii\_evnt) along with a handle (pX\_ts\_rx\_mii\_hndl[2:0]) will be issued before the next record signal for the next packet. The event signal will not be issued for packets that did not meet the time sync event criteria in the TS\_TX\_DEC function. If consecutive record indications occur without an interleaving event indication, then the packet associated with the first record was not a time sync event packet.

The record signal is a single clock pulse indicating that a transmit packet egress has been detected at the associated port MII interface. The handle value is incremented with each time sync event packet and rolls over to zero after 7. There are 8 possible handle values so there can be a maximum of eight time sync event packets “in flight” from the TS\_TX\_DEC to the TS\_TX\_MII block at any given time. The handle value increments only on time sync event packets. The TS\_TX\_MII logic is in the transmit wireside clock domain.

### 14.3.2.3 Device Level Ring (DLR) Support

Device Level Ring (DLR) support is enabled by setting the `dlr_en` bit in the `CPSW_Control` register. When enabled, incoming received DLR packets are detected and sent to queue 3 (highest priority) of the egress port(s). If the host port is the egress port for a DLR packet then the packet is sent on the CPDMA Rx channel selected by the `p0_dlr_cpdma_ch` field in the `P0_Control` register. The supervisor node MAC address feature is supported with the `dlr_unicast` bit in the unicast address table entry.

When set, the `dlr_unicast` bit causes a packet with the matching destination address to be flooded to the `vlan_member_list` minus the receive port and minus the host port (the `port_number` field in the unicast address table entry is a don't care). Matching `dlr_unicast` packets are flooded regardless of whether the packet is a DLR packet or not. The `en_p0_uni_flood` bit in the `ALE_Control` register has no effect on DLR unicast packets. Packets are determined to be DLR packets, as shown:

1. DLR is enabled (`dlr_en` is set in the switch `CPSW_Control` register).
2. One of the following sequences is true:
  - The first packet `ltype` matches `vlan_ltype1` and `pX_vlan_ltype1_en` is set and the second packet `ltype` matches `dlr_ltype`.
  - The first packet `ltype` matches `vlan_ltype2` and `pX_vlan_ltype2_en` is set and the second packet `ltype` matches `dlr_ltype`.
  - The first packet `ltype` matches `vlan_ltype1` and `pX_vlan_ltype1_en` is set and the second packet `ltype` matches `vlan_ltype2` and `pX_vlan_ltype2_en` is set and the third packet `ltype` matches `dlr_ltype`.

### 14.3.2.4 CPDMA RX and TX Interfaces

The CPDMA submodule is a CPPI 3.0 compliant packet DMA transfer controller. The CPPI 3.0 interface is port 0.

After reset, initialization, and configuration the host may initiate transmit operations. Transmit operations are initiated by host writes to the appropriate transmit channel head descriptor pointer contained in the STATERAM block. The transmit DMA controller then fetches the first packet in the packet chain from memory in accordance with CPPI 3.0 protocol. The DMA controller writes the packet into the external transmit FIFO in 64-byte bursts (maximum).

Receive operations are initiated by host writes to the appropriate receive channel head descriptor pointer after host initialization and configuration. The receive DMA controller writes the receive packet data to external memory in accordance with CPPI 3.0 protocol. See the CPPI Buffer Descriptors section for detailed description of Buffer Descriptors

#### 14.3.2.4.1 CPPI Buffer Descriptors

The buffer descriptor is a central part of the 3PSW Ethernet Subsystem and is how the application software describes Ethernet packets to be sent and empty buffers to be filled with incoming packet data.

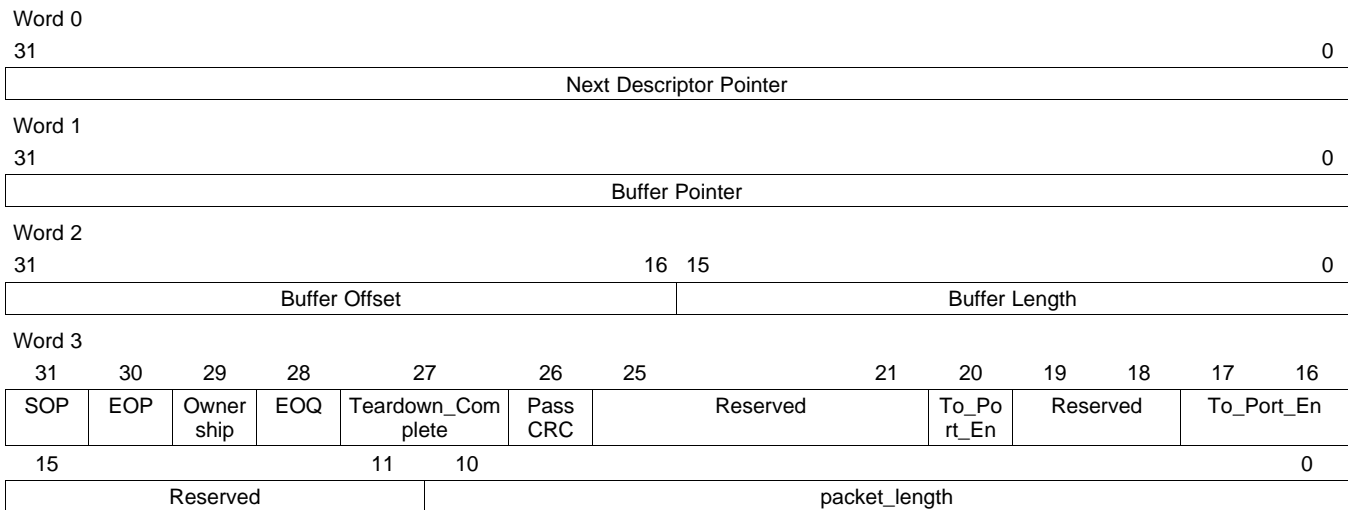

Host Software sends and receives network frames via the CPPI 3.0 compliant host interface. The host interface includes module registers and host memory data structures. The host memory data structures are buffer descriptors and data buffers. Buffer descriptors are data structures that contain information about a single data buffer. Buffer descriptors may be linked together to describe frames or queues of frames for transmission of data and free buffer queues available for received data.

Note: The 8k bytes of Ethernet Subsystem CPPI RAM begin at address 0x4a102000 and end at 0x4a103FFF from the 3PSW perspective. The buffer descriptors programmed to access the CPPI RAM memory should use the address range from 0x4a102000.

##### 14.3.2.4.1.1 TX Buffer Descriptors

A TX buffer descriptor is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

**Figure 14-7. Tx Buffer Descriptor Format**

##### 14.3.2.4.1.1.1 CPPI Tx Data Word – 0

###### Next Descriptor Pointer

The next descriptor pointer points to the 32-bit word aligned memory address of the next buffer descriptor in the transmit queue. This pointer is used to create a linked list of buffer descriptors. If the value of this pointer is zero, then the current buffer is the last buffer in the queue. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC. The value of pNext should never be altered once the descriptor is in an active transmit queue, unless its current value is NULL.

If the pNext pointer is initially NULL, and more packets need to be queued for transmit, the software application may alter this pointer to point to a newly appended descriptor. The EMAC will use the new pointer value and proceed to the next descriptor unless the pNext value has already been read. In this latter case, the transmitter will halt on the transmit channel in question, and the software application may restart it at that time. The software can detect this case by checking for an end of queue (EOQ) condition flag on the updated packet descriptor when it is returned by the EMAC.

##### 14.3.2.4.1.1.2 CPPI Tx Data Word – 1

###### Buffer Pointer

The byte aligned memory address of the buffer associated with the buffer descriptor. The host sets the **buffer\_pointer**. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC.

#### 14.3.2.4.1.1.3 CPPI Tx Data Word – 2

##### Buffer \_Offset

Buffer Offset – Indicates how many unused bytes are at the start of the buffer. A value of 0x0000 indicates that no unused bytes are at the start of the buffer and that valid data begins on the first byte of the buffer. A value of 0x000F (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. The host sets the `buffer_offset` value (which may be zero to the buffer length minus 1). Valid only on sop.

##### Buffer \_Length

Buffer Length – Indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. The host sets the `buffer_length`. The `buffer_length` must be greater than zero.

#### 14.3.2.4.1.1.4 CPPI Tx Data Word – 3

##### Start of Packet (SOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

0 - Not start of packet buffer

1 - Start of packet buffer

##### End of Packet (EOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

0 - Not end of packet buffer.

1 - End of packet buffer.

##### Ownership

When set this flag indicates that all the descriptors for the given packet (from SOP to EOP) are currently owned by the EMAC. This flag is set by the software application on the SOP packet descriptor before adding the descriptor to the transmit descriptor queue. For a single fragment packet, the SOP, EOP, and OWNER flags are all set. The OWNER flag is cleared by the EMAC once it is finished with all the descriptors for the given packet. Note that this flag is valid on SOP descriptors only.

0 - The packet is owned by the host

1 - The packet is owned by the port

##### EOQ

When set, this flag indicates that the descriptor in question was the last descriptor in the transmit queue for a given transmit channel, and that the transmitter has halted. This flag is initially cleared by the software application prior to adding the descriptor to the transmit queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet (the EOP flag is set), and there are no more descriptors in the transmit list (next descriptor pointer is NULL).

The software application can use this bit to detect when the EMAC transmitter for the corresponding channel has halted. This is useful when the application appends additional packet descriptors to a transmit queue list that is already owned by the EMAC. Note that this flag is valid on EOP descriptors only.

- 0 - The Tx queue has more packets to transfer.
- 1 - The Descriptor buffer is the last buffer in the last packet in the queue.

#### **teardown\_Complete**

This flag is used when a transmit queue is being torn down, or aborted, instead of allowing it to be transmitted. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the SOP descriptor of each packet as it is aborted from transmission. Note that this flag is valid on SOP descriptors only. Also note that only the first packet in an unsent list has the TDOWNCMPLT flag set. Subsequent descriptors are not processed by the EMAC.

- 0 - The port has not completed the teardown process.
- 1 - The port has completed the commanded teardown process.

#### **pass\_crc**

This flag is set by the software application in the SOP packet descriptor before it adds the descriptor to the transmit queue. Setting this bit indicates to the EMAC that the 4 byte Ethernet CRC is already present in the packet data, and that the EMAC should not generate its own version of the CRC. When the CRC flag is cleared, the EMAC generates and appends the 4-byte CRC. The buffer length and packet length fields do not include the CRC bytes. When the CRC flag is set, the 4-byte CRC is supplied by the software application and is already appended to the end of the packet data. The buffer length and packet length fields include the CRC bytes, as they are part of the valid packet data. Note that this flag is valid on SOP descriptors only.

- 0 – The CRC is not included with the packet data and packet length.
- 1 – The CRC is included with the packet data and packet length.

#### **to\_port**

To Port – Port number to send the directed packet to. This field is set by the host. This field is valid on SOP. Directed packets go to the directed port, but an ALE lookup is performed to determine untagged egress in VLAN\_AWARE mode.

- 1 – Send the packet to port 1 if to\_port\_en is asserted.
- 2 – Send the packet to port 2 if to\_port\_en is asserted.

#### **To\_port\_enable**

To Port Enable – Indicates when set that the packet is a directed packet to be sent to the to\_port field port number. This field is set by the host. The packet is sent to one port only (index not mask). This bit is valid on SOP.

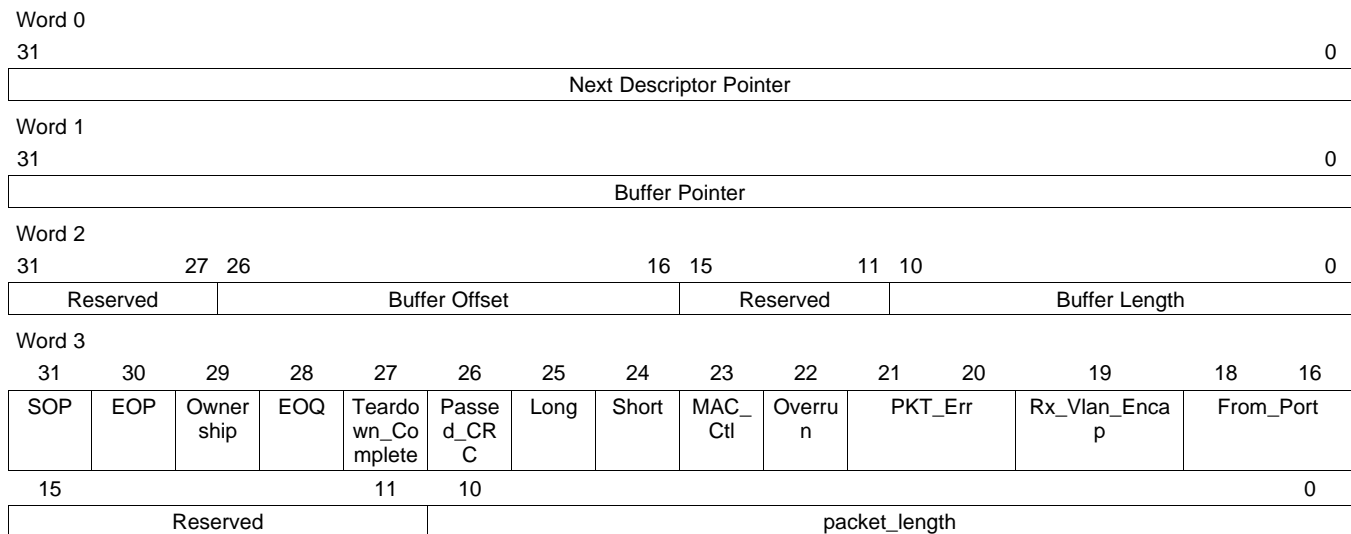

- 0 – not a directed packet
- 1 – directed packet

#### **Packet Length**

Specifies the number of bytes in the entire packet. Offset bytes are not included. The sum of the buffer\_length fields should equal the packet\_length. Valid only on SOP. The packet length must be greater than zero. The packet data will be truncated to the packet length if the packet length is shorter than the sum of the packet buffer descriptor buffer lengths. A host error occurs if the packet length is greater than the sum of the packet buffer descriptor buffer lengths

#### **14.3.2.4.1.2 RX Buffer Descriptors**

An RX buffer descriptor is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

**Figure 14-8. Rx Buffer Descriptor Format**

#### 14.3.2.4.1.2.1 CPPI Rx Data Word – 0

##### **next\_descriptor\_pointer**

The 32-bit word aligned memory address of the next buffer descriptor in the RX queue. This is the mechanism used to reference the next buffer descriptor from the current buffer descriptor. If the value of this pointer is zero then the current buffer is the last buffer in the queue. The host sets the **next\_descriptor\_pointer**.

#### 14.3.2.4.1.2.2 CPPI Rx Data Word – 1

##### **buffer\_pointer**

The byte aligned memory address of the buffer associated with the buffer descriptor. The host sets the **buffer\_pointer**.

#### 14.3.2.4.1.2.3 CPPI Rx Data Word – 2

##### **Buffer\_Offset**

Buffer Offset – Indicates how many unused bytes are at the start of the buffer. A value of 0x0000 indicates that there are no unused bytes at the start of the buffer and that valid data begins on the first byte of the buffer. A value of 0x000F (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. The port writes the **buffer\_offset** with the value from the **rx\_buffer\_offset** register value. The host initializes the **buffer\_offset** to zero for free buffers. The **buffer\_length** must be greater than the **rx\_buffer\_offset** value. The buffer offset is valid only on **sop**.

##### **Buffer\_Length**

Buffer Length – Indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. The host initializes the **buffer\_length**, but the port may overwrite the host initiated value with the actual buffer length value on SOP and/or EOP buffer descriptors. SOP buffer length values will be overwritten if the packet size is less than the size of the buffer or if the offset is nonzero. EOP buffer length values will be overwritten if the entire buffer is not filled up with data. The **buffer\_length** must be greater than zero.

#### 14.3.2.4.1.2.4 CPPI Rx Data Word – 3

##### Start of Packet (SOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on SOP descriptors.

##### End of Packet (EOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on EOP descriptors.

##### Ownership (OWNER) Flag

When set, this flag indicates that the descriptor is currently owned by the EMAC. This flag is set by the software application before adding the descriptor to the receive descriptor queue. This flag is cleared by the EMAC once it is finished with a given set of descriptors, associated with a received packet. The flag is updated by the EMAC on SOP descriptor only. So when the application identifies that the OWNER flag is cleared on an SOP descriptor, it may assume that all descriptors up to and including the first with the EOP flag set have been released by the EMAC. (Note that in the case of single buffer packets, the same descriptor will have both the SOP and EOP flags set.)

##### End of Queue (EOQ) Flag

When set, this flag indicates that the descriptor in question was the last descriptor in the receive queue for a given receive channel, and that the corresponding receiver channel has halted. This flag is initially cleared by the software application prior to adding the descriptor to the receive queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet received (also sets the EOP flag), and there are no more descriptors in the receive list (next descriptor pointer is NULL). The software application can use this bit to detect when the EMAC receiver for the corresponding channel has halted. This is useful when the application appends additional free buffer descriptors to an active receive queue. Note that this flag is valid on EOP descriptors only.

##### Teardown Complete (TDOWNCMPLT) Flag

This flag is used when a receive queue is being torn down, or aborted, instead of being filled with received data. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the descriptor of the first free buffer when the tear down occurs. No additional queue processing is performed.

##### Pass CRC (PASSCRC) Flag

This flag is set by the EMAC in the SOP buffer descriptor if the received packet includes the 4-byte CRC. This flag should be cleared by the software application before submitting the descriptor to the receive queue.

##### Long (Jabber) Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is a jabber frame and was not discarded because the RX\_CEF\_EN bit was set in the MacControl. Jabber frames are frames that exceed the RXMAXLEN in length, and have CRC, code, or alignment errors.

##### Short (Fragment) Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is only a packet fragment and was not discarded because the RX\_CSF\_EN bit was set in the MacControl.

##### Control Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is an EMAC control frame and was not discarded because the RX\_CMF\_EN bit was set in the MacControl.

##### Overrun Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet was aborted due to a receive overrun.

**Pkt\_error Flag**

Packet Contained Error on Ingress –

00 – no error

01 – CRC error on ingress

10 – Code error on ingress

11 – Align error on ingress

**rx\_vlan\_encap**

VLAN Encapsulated Packet – Indicates when set that the packet data contains a 32-bit VLAN header word that is included in the packet byte count. This field is set by the port to be the value of the CPSW control register rx\_vlan\_encap bit

**from\_port**

From Port – Indicates the port number that the packet was received on (ingress to the switch).

**Packet Length**

Specifies the number of bytes in the entire packet. The packet length is reduced to 12-bits. Offset bytes are not included. The sum of the buffer\_length fields should equal the packet\_length. Valid only on SOP.

**14.3.2.4.2 Receive DMA Interface**

The Receive DMA is an eight channel CPPI 3.0 compliant interface. Each channel has a single queue for frame reception.

**14.3.2.4.2.1 Receive DMA Host Configuration**

To configure the Rx DMA for operation the host must perform the following:

- Initialize the receive addresses.
- Initialize the Rx\_HDP Registers to zero.
- Enable the desired receive interrupts in the IntMask register.
- Write the rx\_buffer\_offset register value.
- Setup the receive channel(s) buffer descriptors in host memory as required by CPPI 3.0.
- Enable the RX DMA controller by setting the rx\_en bit in the Rx\_Control register.

**14.3.2.4.2.2 Receive Channel Teardown**

The host commands a receive channel teardown by writing the channel number to the Rx\_Teardown register. When a teardown command is issued to an enabled receive channel the following will occur:

- Any current frame in reception will complete normally.
- The teardown\_complete bit will be set in the next buffer descriptor in the chain

if there is one.

- The channel head descriptor pointer will be cleared to zero
- A receive interrupt for the channel will be issued to the host.
- The host should acknowledge a teardown interrupt with a 0xfffffc acknowledge value.

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete buffer descriptor bit. The port does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with a 0xffffffff acknowledge value (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location to determine if the interrupt was due to a commanded teardown. The read value will be 0xffffffff if the interrupt was due to a teardown command.

#### 14.3.2.4.3 Transmit DMA Interface

The Transmit DMA is an eight channel CPPI 3.0 compliant interface. Priority between the eight queues may be either fixed or round robin as selected by tx\_ptype in the DMAControl register. If the priority type is fixed, then channel 7 has the highest priority and channel 0 has the lowest priority. Round robin priority proceeds from channel 0 to channel 7. Packet Data transfers occur on the TX\_VBUSP interface in 64-byte maximum burst transfers

##### 14.3.2.4.3.1 Transmit DMA Host Configuration

To configure the TX DMA for operation the host must do the following:

- Initialize the Tx\_HDP registers to a zero value.
- Enable the desired transmit interrupts in the IntMask register.
- Setup the transmit channel(s) buffer descriptors in host memory as defined in CPPI 3.0.
- Configure and enable the transmit operation as desired in the TxControl register.
- Write the appropriate Tx\_HDP registers with the appropriate values to start transmit operations.

##### 14.3.2.4.3.2 Transmit Channel Teardown

The host commands a transmit channel teardown by writing the channel number to the Tx\_Teardown register. When a teardown command is issued to an enabled transmit channel the following will occur:

- Any frame currently in transmission will complete normally
- The teardown complete bit will be set in the next sop buffer descriptor (if there is one).
- The channel head descriptor pointer will be set to zero.
- An interrupt will be issued to inform the host of the channel teardown.
- The host should acknowledge a teardown interrupt with a 0xffffffff acknowledge value

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete buffer descriptor bit. The port does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with a 0xffffffff acknowledge value (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location to determine if the interrupt was due to a commanded teardown. The read value will be 0xffffffff if the interrupt was due to a teardown command.

##### 14.3.2.4.4 Transmit Rate Limiting

Transmit operations can be configured to rate limit the transmit data for each transmit priority. Rate limiting is enabled for a channel when the tx\_rlim[7:0] bit associated with that channel is set in the DMAControl register. Rate limited channels must be the highest priority channels. For example, if two rate limited channels are required then tx\_rlim[7:0] should be set to 11000000 with the msb corresponding to channel 7.

When any channels are configured to be rate-limiting, the priority type must be fixed for transmit. Round-robin priority type is not allowed when rate-limiting. Each of the eight transmit priorities has an associated register to control the rate at which the priority is allowed to send data (Tx\_Pri(7..0)\_Rate) when the channel is rate-limiting. Each priority has a send count (pri(7..0)\_send\_cnt[13:0]) and an idle count (pri(7..0)\_idle\_cnt[13:0]). The transfer rate includes the inter-packet gap (12 bytes) and the preamble (8 bytes). The rate in Mbits/second that each priority is allowed to send is controlled by the below equation.

Priority Transfer rate in Mbit/s = ((priN\_idle\_cnt/(priN\_idle\_cnt + priN\_send\_cnt)) \* frequency \* 32

Where the frequency is the CLK frequency.

#### 14.3.2.4.5 Command IDLE

The `cmd_idle` bit in the DMA\_Control register allows CPDMA operation to be suspended. When the idle state is commanded, the CPDMA will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the tx cell fifo will be transmitted. For receive, frames that are detected by the CPDMA after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Commanded idle is similar in operation to emulation control and clock stop.

#### 14.3.2.5 VLAN Aware Mode

The CPSW\_3G is in VLAN aware mode when the CPSW Control register `vlan_aware` bit is set. In VLAN aware mode ports 0 receive packets (out of the CPSW\_3G) may or may not be VLAN encapsulated depending on the CPSW Control register `rx_vlan_encap` bit. The header packet VLAN is generated as described in [Section 14.3.3, Ethernet Mac Sliver \(CPGMAC\\_SL\)](#). Port 0 receive packet data is never modified. VLAN is not removed regardless of the force untagged egress bit for Port 0. VLAN encapsulated receive packets have a 32-bit VLAN header encapsulation word added to the packet data. VLAN encapsulated packets are specified by a set `rx_vlan_encap` bit in the packet buffer descriptor.

Port 0 transmit packets are never VLAN encapsulated (encapsulation is not allowed).

In VLAN aware mode, transmitted packet data is changed depending on the packet type (`pkt_type`), packet priority (`pkt_pri`), and VLAN information as shown in the below tables:

**Figure 14-9. VLAN Header Encapsulation Word**

**Table 14-9. VLAN Header Encapsulation Word Field Descriptions**

Field	Description
HDR_PKT_Priority	Header Packet VLAN priority (Highest priority: 7)
HDR_PKT_CFI	Header Packet VLAN CFI bit.
HDR_PKT_Vid	Header Packet VLAN ID
PKT_Type	Packet Type. Indicates whether the packet is VLAN-tagged, priority-tagged, or non-tagged. 00: VLAN-tagged packet 01: Reserved 10: Priority-tagged packet 11: Non-tagged packet

#### 14.3.2.6 VLAN Unaware Mode

The CPSW\_3G is in VLAN unaware mode when the CPSW Control register `vlan_aware` bit is cleared. Port 0 receive packets (out of the CPSW\_3G) may or may not be VLAN encapsulated depending on the CPSW Control register `rx_vlan_encap` bit. Port 0 transmit packets are never VLAN encapsulated.

#### 14.3.2.7 Address Lookup Engine (ALE)

The address lookup engine (ALE) processes all received packets to determine which port(s) if any that the packet should be forwarded to. The ALE uses the incoming packet received port number, destination address, source address, length/type, and VLAN information to determine how the packet should be forwarded. The ALE outputs the port mask to the switch fabric that indicates the port(s) the packet should be forwarded to. The ALE is enabled when the `ale_enable` bit in the ALE\_Control register is set. All packets are dropped when the `ale_enable` bit is cleared to zero.

In normal operation, the CPGMAC\_SL modules are configured to issue an abort, instead of an end of packet, at the end of a packet that contains an error (runt, frag, oversize, jabber, crc, alignment, code etc.) or at the end of a mac control packet. However, when the CPGMAC\_SL configuration bit(s) cef, csf, or cmf are set, error frames, short frames or mac control frames have a normal end of packet instead of an abort at the end of the packet. When the ALE receives a packet that contains errors (due to a set header error bit), or a mac control frame and does not receive an abort, the packet will be forwarded only to the host port (port 0). No ALE learning occurs on packets with errors or mac control frames. Learning is based on source address and lookup is based on destination address.

The ALE may be configured to operate in bypass mode by setting the ale\_bypass bit in the ALE\_Control register. When in bypass mode, all CPGMAC\_SL received packets are forwarded only to the host port (port 0). Packets from the two ports can be on separate Rx DMA channels by configuring the CPDMA\_Rx\_Ch\_Map register. In bypass mode, the ALE processes host port transmit packets the same as in normal mode. In general, packets would be directed by the host in bypass mode.

The ALE may be configured to operate in OUI deny mode by setting the enable\_oui\_deny bit in the ALE\_Control register. When in OUI deny mode, a packet with a non-matching OUI source address will be dropped unless the destination address matches a multicast table entry with the super bit set. Broadcast packets will be dropped unless the broadcast address is entered into the table with the super bit set. Unicast packets will be dropped unless the unicast address is in the table with block and secure both set (supervisory unicast packet).

Multicast supervisory packets are designated by the super bit in the table entry. Unicast supervisory packets are indicated when block and secure are both set. Supervisory packets are not dropped due to rate limiting, OUI, or VLAN processing.

#### 14.3.2.7.1 Address Table Entry

The ALE table contains 1024 entries. Each table entry represents a free entry, an address, a VLAN, an address/VLAN pair, or an OUI address. Software should ensure that there are not double address entries in the table. The double entry used would be indeterminate. Reserved table bits must be written with zeroes.

Source Address learning occurs for packets with a unicast, multicast or broadcast destination address and a unicast or multicast (including broadcast) source address. Multicast source addresses have the group bit (bit 40) cleared before ALE processing begins, changing the multicast source address to a unicast source address. A multicast address of all ones is the broadcast address which may be added to the table. A learned unicast source address is added to the table with the following control bits:

**Table 14-10. Learned Address Control Bits**

unicast_type	11
Block	0
Secure	0

If a received packet has a source address that is equal to the destination address then the following occurs:

- The address is learned if the address is not found in the table.
- The address is updated if the address is found.
- The packet is dropped.

##### 14.3.2.7.1.1 Free Table Entry

**Table 14-11. Free (Unused) Address Table Entry Bit Values**

71:62	61:60	59:0
Reserved	Entry Type (00)	Reserved

### 14.3.2.7.1.2 Multicast Address Table Entry

**Table 14-12. Multicast Address Table Entry Bit Values**

71:70	68:66	65	64	63:62	61:60	59:48	47:0
Reserved	Port Mask	Super	Reserved	Mcast Fwd State	Entry Type (01)	Reserved	Multicast Address

#### Table Entry Type

00: Free Entry

01: Address Entry : unicast or multicast determined by dest **address bit 40** .

10: VLAN entry

11: VLAN Address Entry : unicast or multicast determined by **address bit 40**.

#### Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

#### Port Mask(2:0) (PORT\_MASK)

This three bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

#### Multicast Forward State (MCAST\_FWD\_STATE)

Multicast Forward State – Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit port\_mask has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00: Forwarding

01: Blocking/Forwarding/Learning

10: Forwarding/Learning

11: Forwarding

The forward state test returns a true value if both the Rx and Tx ports are in the required state.

#### Table Entry Type (ENTRY\_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

#### Packet Address (MULTICAST\_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

### 14.3.2.7.1.3 VLAN/Multicast Address Table Entry

**Table 14-13. VLAN/Multicast Address Table Entry Bit Values**

71:69	68:66	65	64	63:62	61:60	59:48	47:0
Reserved	Port Mask	Super	Reserved	Mcast Fwd State	Entry Type (11)	vlan_id	Multicast Address

### Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

### Port Mask(2:0) (PORT\_MASK)

This three bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

### Multicast Forward State (MCAST\_FWD\_STATE)

Multicast Forward State – Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit port\_mask has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00 – Forwarding

01 – Blocking/Forwarding/Learning

10 – Forwarding/Learning

11 – Forwarding

The forward state test returns a true value if both the Rx and Tx ports are in the required state.

### Table Entry Type (ENTRY\_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

11: VLAN address entry. Unicast or multicast determined by address bit 40.

### VLAN ID (VLAN\_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

### Packet Address (MULTICAST\_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

#### 14.3.2.7.1.4 Unicast Address Table Entry

**Table 14-14. Unicast Address Table Entry Bit Values**

71:70	69	68	67:66	65	64	63:62	61:60	59:48	47:0
Reserved	DLR Unicast	Reserved	Port Number	Block	Secure	Unicast Type (00) or (X1)	Entry Type (01)	Reserved	Unicast Address

### DLR Unicast

DLR Unicast – When set, this bit indicates that the address is a Device Level Ring (DLR) unicast address. Received packets with a matching destination address will be flooded to the vlan\_member\_list (minus the receive port and the host port). The port\_number field is a don't care when this bit is set. Matching packets received on port 1 egress on port 2. Matching packets received on port 2 egress on port 1. Matching packets received on port 0 egress on ports 1 and 2.

### Port Number (PORT\_NUMBER)

Port Number – This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).

### Block (BLOCK)

Block – The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 – Address is not blocked.

1 – Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

### Secure (SECURE)

Secure – This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry port\_number.

0 – Received port number is a don't care.

1 – Drop the packet if the received port is not the secure port for the source address and do not update the address (block must be zero)

### Unicast Type (UNICAST\_TYPE)

Unicast Type – This field indicates the type of unicast address the table entry contains.

00 – Unicast address that is not ageable.

01 – Ageable unicast address that has not been touched.

10 – OUI address - lower 24-bits are don't cares (not ageable).

11 – Ageable unicast address that has been touched.

### Table Entry Type (ENTRY\_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

### Packet Address (UNICAST\_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

#### 14.3.2.7.1.5 OUI Unicast Address Table Entry

**Table 14-15. OUI Unicast Address Table Entry Bit Values**

71:64	63:62	61:60	59:48	47:24	23:0
Reserved	Unicast Type (10)	Entry Type (01)	Reserved	Unicast OUI	Reserved

### Unicast Type (UNICAST\_TYPE)

Unicast Type – This field indicates the type of unicast address the table entry contains.

00 – Unicast address that is not ageable.

01 – Ageable unicast address that has not been touched.

10 – OUI address - lower 24-bits are don't cares (not ageable).

11 – Ageable unicast address that has been touched.

### Table Entry Type (ENTRY\_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

### Packet Address (UNICAST\_OUI)

For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup.

#### 14.3.2.7.1.6 VLAN/Unicast Address Table Entry

**Table 14-16. Unicast Address Table Entry Bit Values**

71:68	67:66	65	64	63:62	61:60	59:48	47:0
Reserved	Port Number	Block	Secure	Unicast Type (00) or (X1)	Entry Type (11)	vlan_id	Unicast Address

### Port Number (PORT\_NUMBER)

Port Number – This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).]

### Block (BLOCK)

Block – The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 – Address is not blocked.

1 – Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

### Secure (SECURE)

Secure – This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry port\_number.

0 – Received port number is a don't care.

1 – Drop the packet if the received port is not the secure port for the source address and do not update the address (block must be zero)

### Unicast Type (UNICAST\_TYPE)

Unicast Type – This field indicates the type of unicast address the table entry contains.

00 – Unicast address that is not ageable.

01 – Ageable unicast address that has not been touched.

10 – OUI address - lower 24-bits are don't cares (not ageable).

11 – Ageable unicast address that has been touched.

### Table Entry Type (ENTRY\_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

11 – VLAN address entry. Unicast or multicast determined by address bit 40.

### VLAN ID (VLAN\_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

**Packet Address (UNICAST\_ADDRESS)**

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

**14.3.2.7.1.7 VLAN Table Entry**
**Table 14-17. VLAN Table Entry**

<b>71:62</b>	<b>61:60</b>	<b>59:48</b>	<b>47:27</b>	<b>26:24</b>	<b>23:19</b>	<b>18:16</b>	<b>15:11</b>	<b>10:8</b>	<b>7:3</b>	<b>2:0</b>
Reserved	Entry Type (10)	vlan_id	Reserved	Force Untagged Egress	Reserved	Reg Mcast Flood Mask	Reserved	Unreg Mcast Flood Mask	Reserved	Vlan Member List

**Table Entry Type (ENTRY\_TYPE)**

10: VLAN entry

**VLAN ID (VLAN\_ID)**

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

**Force Untagged Packet Egress (FORCE\_UNTAGGED\_EGRESS)**

This field causes the packet VLAN tag to be removed on egress (except on port 0).

**Registered Multicast Flood Mask (REG\_MCAST\_FLOOD\_MASK)**

Mask used for multicast when the multicast address is found

**Unregistered Multicast Flood Mask (UNREG\_MCAST\_FLOOD\_MASK)**

Mask used for multicast when the multicast address is not found

**VLAN Member List (VLAN\_MEMBER\_LIST)**

This three bit field indicates which port(s) are members of the associated VLAN.

**14.3.2.7.2 Packet Forwarding Processes**

There are four processes that an incoming received packet may go through to determine packet forwarding. The processes are Ingress Filtering, VLAN\_Aware Lookup, VLAN\_Unaware Lookup, and Egress.

Packet processing begins in the Ingress Filtering process. Each port has an associated packet forwarding state that can be one of four values (Disabled, Blocked, Learning, or Forwarding). The default state for all ports is disabled. The host sets the packet forwarding state for each port. The receive packet processes are described in the following sections.

In the packet ingress process (receive packet process), there is a forward state test for unicast destination addresses and a forward state test for multicast addresses. The multicast forward state test indicates the port states required for the receiving port in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state for the packet to be forwarded for transmission. The mcast\_fwd\_state indicates the required port state for the receiving port as indicated in [Table 14-13](#).

The unicast forward state test indicates the port state required for the receiving port in order to forward the unicast packet. The transmit port must be in the Forwarding state in order to forward the packet. The block and secure bits determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state. The transmit port must be in the Forwarding state regardless. The forward state test used in the ingress process is determined by the destination address packet type (multicast/unicast).

In general, packets received with errors are dropped by the address lookup engine without learning, updating, or touching the address. The error condition and the abort are indicated by the CPGMAC\_SL to the ALE. Packets with errors may be passed to the host (not aborted) by a CPGMAC\_SL port if the port has a set rx\_cmf\_en, rx\_cef\_en, or rx\_csf\_en bit(s).

Error packets that are passed to the host by the CPGMAC\_SL are considered to be bypass packets by the ALE and are sent only to the host. Error packets do not learn, update, or touch addresses regardless of whether they are aborted or sent to the host. Packets with errors received by the host are forwarded as normal.

The following control bits are in the CPGMAC\_SL1/2\_MacControl register.

rx\_cef\_en: This CPGMAC\_SL control bit enables frames that are fragments, long, jabber, CRC, code, and alignment errors to be forwarded.

rx\_csf\_en: This CPGMAC\_SL bit enables short frames to be forwarded.

rx\_cmf\_en: This CPGMAC\_SL control bit enables mac control frames to be forwarded.

#### 14.3.2.7.2.1 Ingress Filtering Process

If (Rx port_state is Disabled) then discard the packet
if (directed packet) then use directed port number and go to Egress process
if ((ale_bypass or error packet) and (host port is not the receive port)) then use host portmask and go to Egress process
if (((block) and (unicast source address found)) or ((block) and (unicast destination address found))) then discard the packet
if ((enable_rate_limit) and (rate limit exceeded) and (not rate_limit_tx)) then if (((mcast/bcast destination address found) and (not super)) or (mcast/bcast destination address not found)) then discard the packet
if ((not forward state test valid) and (destination address found)) then discard the packet to any port not meeting the requirements <ul style="list-style-type: none"> <li>• Unicast destination addresses use the unicast forward state test and multicast destination addresses use the multicast forward state test.</li> </ul>
if ((destination address not found) and ((not transmit port forwarding) or (not receive port forwarding))) then discard the packet to any ports not meeting the above requirements
if (source address found) and (secure) and (receive port number != port_number) then discard the packet
if ((not super) and (drop_untagged) and ((non-tagged packet) or ((priority tagged) and not(en_vid0_mode))) then discard the packet
If (VLAN_Unaware) force_untagged_egress = "000000" reg_mcast_flood_mask = "111111" unreg_mcast_flood_mask = "111111" vlan_member_list = "111111" else if (VLAN not found) force_untagged_egress = unknown_force_untagged_egress reg_mcast_flood_mask = unknown_reg_mcast_flood_mask unreg_mcast_flood_mask = unknown_unreg_mcast_flood_mask vlan_member_list = unknown_vlan_member_list else force_untagged_egress = found_force_untagged_egress reg_mcast_flood_mask = found_reg_mcast_flood_mask unreg_mcast_flood_mask = found_unreg_mcast_flood_mask vlan_member_list = found_vlan_member_list
if ((not super) and (vid_ingress_check) and (Rx port is not VLAN member)) then discard the packet

if ((enable_auth_mode) and (source address not found) and not(destination address found and (super))) then discard the packet
if (destination address equals source address) then discard the packet
if (vlan_aware) goto VLAN_Aware_Lookup process else goto VLAN_Unaware_Lookup process

#### 14.3.2.7.2.2 VLAN\_Aware Lookup Process

if ((unicast packet) and (destination address found with or without VLAN) and dlr_unicast) then portmask is the vlan_member_list less the host port and goto Egress process
if ((unicast packet) and (destination address found with or without VLAN) and (not super)) then portmask is the logical "AND" of the port_number and the vlan_member_list and goto Egress process
if ((unicast packet) and (destination address found with or without VLAN) and (super)) then portmask is the port_number and goto Egress process
if (Unicast packet) # destination address not found then portmask is vlan_member_list less host port and goto Egress process
if ((Multicast packet) and (destination address found with or without VLAN) and (not super)) then portmask is the logical "AND" of reg_mcast_flood_mask and found destination address/VLAN portmask (port_mask) and vlan_member_list and goto Egress process
if ((Multicast packet) and (destination address found with or without VLAN) and (super)) then portmask is the port_mask and goto Egress process
if (Multicast packet) # destination address not found then portmask is the logical "AND" of unreg_mcast_flood_mask and vlan_member_list then goto Egress process
if (Broadcast packet) then use found vlan_member_list and goto Egress process

#### 14.3.2.7.2.3 VLAN\_Unaware Lookup Process

if ((unicast packet) and (destination address found with or without VLAN) and dlr_unicast) then portmask is the vlan_member_list less the host port and goto Egress process
if ((unicast packet) and (destination address found with or without VLAN) and (not super)) then portmask is the logical "AND" of the port_number and the vlan_member_list and goto Egress process
if ((unicast packet) and (destination address found with or without VLAN) and (super)) then portmask is the port_number and goto Egress process
if (Unicast packet) # destination address not found then portmask is vlan_member_list less host port and goto Egress process
if ((Multicast packet) and (destination address found with or without VLAN) and (not super)) then portmask is the logical "AND" of reg_mcast_flood_mask and found destination address/VLAN portmask (port_mask) and vlan_member_list and goto Egress process
if ((Multicast packet) and (destination address found with or without VLAN) and (super)) then portmask is the port_mask and goto Egress process
if (Multicast packet) # destination address not found then portmask is the logical "AND" of unreg_mcast_flood_mask and vlan_member_list then goto Egress process

if (Broadcast packet) then use found_vlan_member_list and goto Egress process
--

#### 14.3.2.7.2.4 Egress Process

Clear Rx port from portmask (don't send packet to Rx port).
Clear disabled ports from portmask.
if ((enable_oui_deny) and (OUI source address not found) and (not ale_bypass) and (not error packet) and not ((mcast destination address) and (super))) then Clear host port from portmask
if ((enable_rate_limit) and (rate_limit_tx)) then if (not super) and (rate limit exceeded on any tx port) then clear rate limited tx port from portmask If address not found then super cannot be set.
If portmask is zero then discard packet
Send packet to portmask ports.

#### 14.3.2.7.3 Learning/Updating/Touching Processes

The learning, updating, and touching processes are applied to each receive packet that is not aborted. The processes are concurrent with the packet forwarding process. In addition to the following, a packet must be received without error in order to learn/update/touch an address.

##### 14.3.2.7.3.1 Learning Process

If (not(Learning or Forwarding) or (enable_auth_mode) or (packet error) or (no_learn)) then do not learn address
if ((Non-tagged packet) and (drop_untagged)) then do not learn address
if ((vlan_aware) and (VLAN not found) and (unknown_vlan_member_list = "000")) then do not learn address
if ((vid_ingress_check) and (Rx port is not VLAN member) and (VLAN found)) then do not learn address
if ((source address not found) and (vlan_aware) and not(learn_no_vid)) then learn address with VLAN
if ((source address not found) and ((not vlan_aware) or (vlan_aware and learn_no_vid))) then learn address without VLAN

##### 14.3.2.7.3.2 Updating Process

if (dlr_unicast) then do not update address
If (not(Learning or Forwarding) or (enable_auth_mode) or (packet error) or (no_sa_update)) then do not update address
if ((Non-tagged packet) and (drop_untagged)) then do not update address
if ((vlan_aware) and (VLAN not found) and (unknown_vlan_member_list = "000")) then do not update address

if ((vid_ingress_check) and (Rx port is not VLAN member) and (VLAN found)) then do not update address
if ((source address found) and (receive port number != port_number) and (secure or block)) then do not update address
if ((source address found) and (receive port number != port_number)) then update address

### 14.3.2.7.3.3 Touching Process

if ((source address found) and (ageable) and (not touched)) then set touched
---

### 14.3.2.8 Packet Priority Handling

Packets are received on three ports, two of which are CPGMAC\_SL Ethernet ports and the third port is the CPPI host port. Received packets have a received packet priority (0 to 7 with 7 being the highest priority). The received packet priority is determined as shown:

1. If the first packet LTYPE = 0x8100 then the received packet priority is the packet priority (VLAN tagged and priority tagged packets).
2. If the first packet LTYPE = 0x0800 and byte 14 (following the LTYPE) is equal to 0x45 then the received packet priority is the 6-bit TOS field in byte 15 (upper 6-bits) mapped through the port's DSCP priority mapping register (IPV4 packet).
3. The received packet priority is the source (ingress) port priority (untagged non-IPV4 packet).

The received packet priority is mapped through the receive ports associated "packet priority to header packet priority mapping register" to obtain the header packet priority (the CPDMA Rx and Tx nomenclature is reversed from the CPGMAC\_SL nomenclature for legacy reasons). The header packet priority is mapped through the "header priority to switch priority mapping register" to obtain the hardware switch priority (0 to 3 with 3 being the highest priority). The header packet priority is then used as the actual transmit packet priority if the VLAN information is to be sent on egress.

### 14.3.2.9 FIFO Memory Control

Each of the three CPSW\_3G ports has an identical associated FIFO. Each FIFO contains a single logical receive (ingress) queue and four logical transmit queues (priority 0 through 3). Each FIFO memory contains 20,480 bytes (20k) total organized as 2560 by 64-bit words contained in a single memory instance. The FIFO memory is used for the associated port transmit and receive queues. The tx\_max\_blks field in the FIFO's associated Max\_Blks register determines the maximum number of 1k FIFO memory blocks to be allocated to the four logical transmit queues (transmit total).

The rx\_max\_blks field in the FIFO's associated Max\_Blks register determines the maximum number of 1k memory blocks to be allocated to the logical receive queue. The tx\_max\_blks value plus the rx\_max\_blks value must sum to 20 (the total number of blocks in the FIFO). If the sum were less than 20 then some memory blocks would be unused. The default is 17 (decimal) transmit blocks and three receive blocks. The FIFO's follow the naming convention of the Ethernet ports. Host Port is Port0 and External Ports are Port1,2

### 14.3.2.10 FIFO Transmit Queue Control

There are four transmit queues in each transmit FIFO. Software has some flexibility in determining how packets are loaded into the queues and on how packet priorities are selected for transmission (how packets are removed and transmitted from queues). All ports on the switch have identical FIFO's. For the purposes of the below the transmit FIFO is switch egress even though the port 0 transmit FIFO is connected to the CPDMA receive (also switch egress). The CPDMA nomenclature is reversed from the CPGMAC\_SL nomenclature due to legacy reasons.

### 14.3.2.10.1 Normal Priority Mode

When operating in normal mode, lower priority frames are dropped before higher priority frames. The intention is to give preference to higher priority frames. Priority 3 is the highest priority and is allowed to fill the FIFO. Priority 2 will drop packets if the packet is going to take space in the last 2k available. Priority 1 will drop packets if the packet is going to take space in the last 4k available. Priority 0 will drop packets if the packet is going to take space in the last 6k available. If fewer than 4 priorities are to be implemented then the priorities should be mapped such that the highest priorities are used.

For example, if two priorities are going to be used then all packets should be mapped to priorities 3 and 2 and priorities 1 and 0 should be unused. Priority escalation may be used in normal priority mode if desired. Normal priority mode is configured as described below:

- Select normal priority mode by setting `tx_in_sel[1:0] = 00` for all ports (default value in `P0/1/2_Tx_In_Ctl`)
- Configure priority mapping to use only the highest priorities if less than 4 priorities are used. Refer to the Packet Priority Handling section of this chapter.

### 14.3.2.10.2 Dual Mac Mode

When operating in dual mac mode the intention is to transfer packets between ports 0 and 1 and ports 0 and 2, but not between ports 1 and 2. Each `CPGMAC_SL` appears as a single MAC with no bridging between MAC's. Each `CPGMAC_SL` has at least one unique (not the same) mac address.

Dual mac mode is configured as described below:

- Set the `ale_vlan_aware` bit in the `ALE_Control` register. This bit configures the ALE to process in vlan aware mode. The `CPSW_3G vlan aware` bit (`vlan_aware` in `CPSW_Control`) determines how packets VLAN's are processed on `CPGMAC_SL` egress and does not affect how the ALE processes packets or the packet destination. The `CPSW_3G vlan aware` bit may be set or not as required (must be set if VLAN's are to exit the switch).

- **Configure the Port 1 to Port 0 VLAN**

Add a VLAN Table Entry with ports 0 and 1 as members (clear the flood masks).

Add a VLAN/Unicast Address Table Entry with the Port1/0 VLAN and a port number of 0. Packets received on port 1 with this unicast address will be sent only to port 0 (egress). If multiple mac addresses are desired for this port then multiple entries of this type may be configured.

- **Configure the Port 2 to Port 0 VLAN**

Add a VLAN Table Entry with ports 0 and 2 as members (clear the flood masks).

Add a VLAN/Unicast Address Table Entry with the Port2/0 VLAN and a port number of 0. Packets received on port 2 with this unicast address will be sent only to port 0 (egress). If multiple mac addresses are desired for this port then multiple entries of this type may be configured.

- Packets from the host (port 0) to ports 1 and 2 should be directed. If directed packets are not desired then VLAN with addresses can be added for both destination ports.
- Select the dual mac mode on the port 0 FIFO by setting `tx_in_sel[1:0] = 01` in `P0_Tx_In_Ctl`. The intention of this mode is to allow packets from both ethernet ports to be written into the FIFO without one port starving the other port.
- The priority levels may be configured such that packets received on port 1 egress on one CPDMA RX channel while packets received on port 2 egress on a different CPDMA RX channel.

### 14.3.2.10.3 Rate Limit Mode

Rate-limit mode is intended to allow some CPDMA transmit (switch ingress) channels and some `CPGMAC_SL` FIFO priorities (switch egress) to be rate-limited. Non rate-limited traffic (bulk traffic) is allowed on non rate-limited channels and FIFO priorities. The bulk traffic does not impact the rate-limited traffic. Rate-limited traffic must be configured to be sent to rate-limited queues (via packet priority handling).

The allocated rates for rate-limited traffic must not be oversubscribed. For example, if port 1 is sending 15% rate limited traffic to port 2 priority 3, and port 0 is also sending 10% rate-limited traffic to port 2 priority 3, then the port 2 priority 3 egress rate must be configured to be 25% plus a percent or two for margin. The switch must be configured to allow some percentage of non rate-limited traffic. Non-rate-limited traffic must be configured to be sent to non rate-limited queues. No packets from the host should be dropped, but non rate-limited traffic received on an ethernet port can be dropped. Rate-limited mode is configured as shown:

- Set `tx_in_sel[1:0] = 10` in `P1/2_Tx_In_Ctl` to enable ports 1 and 2 transmit FIFO inputs to be configured for rate-limiting queues. Enabling a queue to be rate-limiting with this field affects only the packet being loaded into the FIFO, it does not configure the transmit for queue shaping.
- Configure the number of rate-limited queues for port 1 and 2 transmit FIFO's by setting the `tx_rate_en[3:0]` field in `P1/2_Tx_In_Ctl`. Rate limited queues must be the highest number. For example, if there are two rate limited queues then 1100 would be written to this field for priorities 3 and 2. This field enables the FIFO to allow rate-limited traffic into rate-limited queues while discriminating against non rate-limited queues.
- Set `p1_priN_shape_en` and `p2_priN_shape_en` in the `CPSW_3G_PTYPE` register. These bits determine which queues actually shape the output data stream. In general, the same priorities that are set in `tx_rate_en` are set in these bits as well, but the FIFO input and output enable bits are separate to allow rate-limiting from the host to non shaped channels if desired. When queue shaping is not enabled for a queue then packets are selected for egress based on priority. When queue shaping is enabled then packets are selected for egress based on queue percentages. If shaping is required on a single queue then it must be priority 3 (priorities 2, 1 and 0 are strict priority). If shaping is required on two queues then it must be on priorities 2 and 3 (priorities 1 and 0 are strict priority). If shaping is required on three queues then it must be priorities 3, 2, and 1 (priority 0 would then get the leftovers). Priority shaping follows the requirements in the IEEE P802.1Qav/D6.0 specification. Priority shaping is not compatible with priority escalation (escalation must be disabled).
- `P0_Tx_In_Ctl[1:0]` should remain at the default 00 value. Port 0 egress (CPDMA RX) should not be rate-limited.
- The CPDMA is configured for rate-limited transmit (switch ingress) channels by setting the highest bits of the `tx_rlim[7:0]` field in the CPDMA `DMA_Control` register. If there are two rate limited channels then `tx_rlim[7:0] = 11000000` (the rate limited channels must be the highest priorities). Also, `tx_ptype` in the `DMA_Control` register must be set (fixed priority mode). Rate limited channels must go to rate-limited FIFO queues, and the FIFO queue rate must not be oversubscribed.

#### 14.3.2.11 Packet Padding

VLAN tagged ingress packets of 64 to 67-bytes will be padded to 64-bytes on egress (all ports) if the VLAN is removed on egress.

#### 14.3.2.12 Flow Control

There are two types of switch flow control – CPPI port flow control and Ethernet port flow control. The CPPI and Ethernet port naming conventions for data flow into and out of the switch are reversed. For the CPPI port (port 0), transmit operations move packets from external memory into the switch and then out to either or both Ethernet transmit ports (ports 1 and 2). CPPI receive operations move packets that were received on either or both Ethernet receive ports to external memory.

##### 14.3.2.12.1 CPPI Port Flow Control

The CPPI port has flow control available for transmit (switch ingress). CPPI receive operations (switch egress) do not require flow control. CPPI Transmit flow control is initiated when enabled and triggered. CPPI transmit flow control is enabled by setting the `p0_flow_en` bit in the **CPSW\_Flow\_Control** register. CPPI transmit flow control is enabled by default on reset because host packets should not be dropped in any mode of operation.

### 14.3.2.12.2 Ethernet Port Flow Control

The Ethernet ports have flow control available for transmit and receive. Transmit flow control stops the Ethernet port from transmitting packets to the wire (switch egress) in response to a received pause frame. Transmit flow control does not depend on FIFO usage.

The ethernet ports have flow control available for receive operations (packet ingress). Ethernet port receive flow control is initiated when enabled and triggered. Packets received on an ethernet port can be sent to the other ethernet port or the CPPI port (or both). Each destination port can trigger the receive ethernet port flow control. An ethernet destination port triggers another ethernet receive flow control when the destination port is full.

When a packet is received on an ethernet port interface with enabled flow control the below occurs:

- The packet will be sent to all ports that currently have room to take the entire packet.
- The packet will be retried until successful to all ports that indicate they don't have room for the packet.

The flow control trigger to the CPGMAC\_SL will be asserted until the packet has been sent, and there is room in the logical receive FIFO for packet runout from another flow control trigger (**rx\_pkt\_cnt** = 0). Ethernet port receive flow control is disabled by default on reset. Ethernet port receive flow control requires that the **rx\_flow\_en** bit in the associated CPGMAC\_SL be set to one.

When receive flow control is enabled on a port, the port's associated FIFO block allocation must be adjusted. The port RX allocation must increase from the default three blocks to accommodate the flow control runout. A corresponding decrease in the TX block allocation is required. If a sending port ignores a pause frame then packets may overrun on receive (and be dropped) but will not be dropped on transmit. If flow control is disabled for gmii ports, then any packets that are dropped are dropped on transmit and not on receive.

#### 14.3.2.12.2.1 Receive Flow Control

When enabled and triggered, receive flow control is initiated to limit the CPGMAC\_SL from further frame reception. Half-duplex mode receive flow control is collision based while full duplex mode issues 802.3X pause frames. In either case, receive flow control prevents frame reception by issuing the flow control appropriate for the current mode of operation. Receive flow control is enabled by the **rx\_flow\_en** bit in the **MacControl** register. Receive flow control is triggered (when enabled) when the **RX\_FLOW\_TRIGGER** input is asserted. The CPGMAC\_SL is configured for collision or IEEE 802.3X flow control via the **fullduplex** bit in the **MacControl** register.

##### 14.3.2.12.2.1.1 Collision Based Receive Buffer Flow Control

Collision-based receive buffer flow control provides a means of preventing frame reception when the port is operating in half-duplex mode (**fullduplex** is cleared in **MacControl**). When receive flow control is enabled and triggered, the port will generate collisions for received frames. The jam sequence transmitted will be the twelve byte sequence C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3 (hex). The jam sequence will begin no later than approximately as the source address starts to be received. Note that these forced collisions will not be limited to a maximum of 16 consecutive collisions, and are independent of the normal back-off algorithm. Receive flow control does not depend on the value of the incoming frame destination address. A collision will be generated for any incoming packet, regardless of the destination address.

##### 14.3.2.12.2.1.2 IEEE 802.3X Based Receive Flow Control

IEEE 802.3x based receive flow control provides a means of preventing frame reception when the port is operating in full-duplex mode (**fullduplex** is set in **MacControl**). When receive flow control is enabled and triggered, the port will transmit a pause frame to request that the sending station stop transmitting for the period indicated within the transmitted pause frame.

The CPGMAC\_SL will transmit a pause frame to the reserved multicast address at the first available opportunity (immediately if currently idle, or following the completion of the frame currently being transmitted). The pause frame will contain the maximum possible value for the pause time (0xFFFF). The MAC will count the receive pause frame time (decrements 0xFF00 down to zero) and retransmit an outgoing pause frame if the count reaches zero. When the flow control request is removed, the MAC will transmit a pause frame with a zero pause time to cancel the pause request.

Note that transmitted pause frames are only a request to the other end station to stop transmitting. Frames that are received during the pause interval will be received normally (provided the Rx FIFO is not full).

Pause frames will be transmitted if enabled and triggered regardless of whether or not the port is observing the pause time period from an incoming pause frame.

The CPGMAC\_SL will transmit pause frames as described below:

- The 48-bit reserved multicast destination address 01.80.C2.00.00.01.
- The 48-bit source address — SL\_SA(47:0).
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause time value FF.FF. A pause-quantum is 512 bit-times. Pause frames sent to cancel a pause request will have a pause time value of 00.00.
- Zero padding to 64-byte data length (The CPGMAC\_SL will transmit only 64 byte pause frames).
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

If **rx\_flow\_en** is cleared to zero while the pause time is nonzero, then the pause time will be cleared to zero and a zero count pause frame will be sent.

#### 14.3.2.12.2.2 Transmit Flow Control

Incoming pause frames are acted upon, when enabled, to prevent the CPGMAC\_SL from transmitting any further frames. Incoming pause frames are only acted upon when the **fullduplex** and **tx\_flow\_en** bits in the **MacControl** register are set. Pause frames are not acted upon in half-duplex mode. Pause frame action will be taken if enabled, but normally the frame will be filtered and not transferred to memory.

MAC control frames will be transferred to memory if the **rx\_cmf\_en** (Copy MAC Frames) bit in the **MacControl** register is set. The **tx\_flow\_en** and **fullduplex** bits effect whether or not MAC control frames are acted upon, but they have no effect upon whether or not MAC control frames are transferred to memory or filtered.

Pause frames are a subset of MAC Control Frames with an opcode field=0x0001. Incoming pause frames will only be acted upon by the port if:

- **tx\_flow\_en** is set in **MacControl**, and
- the frame's length is 64 to **rx\_maxlen** bytes inclusive, and
- the frame contains no crc error or align/code errors.

The pause time value from valid frames will be extracted from the two bytes following the opcode. The pause time will be loaded into the port's transmit pause timer and the transmit pause time period will begin.

If a valid pause frame is received during the transmit pause time period of a previous transmit pause frame then:

- if the destination address is not equal to the reserved multicast address or any enabled or disabled unicast address, then the transmit pause timer will immediately expire, or
- if the new pause time value is zero then the transmit pause timer will immediately expire, else
- the port transmit pause timer will immediately be set to the new pause frame pause time value. (Any remaining pause time from the previous pause frame will be discarded).

If **tx\_flow\_en** in **MacControl** is cleared, then the pause-timer will immediately expire.

The port will not start the transmission of a new data frame any sooner than 512-bit times after a pause frame with a non-zero pause time has finished being received (**MRXDV** going inactive). No transmission will begin until the pause timer has expired (the port may transmit pause frames in order to initiate outgoing flow control). Any frame already in transmission when a pause frame is received will be completed and unaffected.

Incoming pause frames consist of the below:

- A 48-bit destination address equal to:
- The reserved multicast destination address 01.80.C2.00.00.01, or
- The SL\_SA(47:0) input mac source address.
- The 48-bit source address of the transmitting device.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause\_time. A pause-quantum is 512 bit-times.
- Padding to 64-byte data length.
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

The padding is required to make up the frame to a minimum of 64 bytes. The standard allows pause frames longer than 64 bytes to be discarded or interpreted as valid pause frames. The CPGMAC\_SL will recognize any pause frame between 64 bytes and **rx\_maxlen** bytes in length.

#### 14.3.2.13 Packet Drop Interface

The packet drop interface supports an external packet drop engine. The port 1 (and port 2) CPGMAC\_SL receive FIFO VBUSP interface signals are CPSW\_3G outputs. The receive packet interface has an associated packet drop input P1\_RFIFO\_DROP (P2\_RFIFO\_DROP). An external packet drop engine may “snoop” the received packet header and data to determine whether or not the packet should be dropped.

If the packet is to be dropped the external logic must assert the drop signal by no later than the second clock after the end of packet (or abort) indication from the CPGMAC\_SL. The drop signal should remain asserted until the second clock after the end of packet (or abort) indication. If the packet is not to be dropped then the drop signal should remain deasserted. The CPGMAC\_SL section contains more information on the receive FIFO VBUSP interface signals and end of packet indication.

#### 14.3.2.14 Short Gap

The port 1 (and port 2) transmit inter-packet gap (IPG) may be shortened by eight bit times when enabled and triggered. The **tx\_short\_gap\_en** bit in the **SL1\_MacControl (SL2\_MacControl)** register enables the gap to be shortened when triggered. The condition is triggered when the port 1 (port 2) transmit FIFO has a user defined number of FIFO blocks used. The port 1 transmit FIFO blocks used determines if the port 1 gap is shortened, and the port 2 transmit FIFO blocks used determines if the port 2 gap is shortened. The **CPSW\_Gap\_Thresh** register value determines the port 1 short gap threshold, and the **CPSW\_Gap\_Thresh** register value determines the port 2 short gap threshold.

#### 14.3.2.15 Switch Latency

The CPSW\_3G is a store and forward switch. The switch latency is defined as the amount of time between the end of packet reception of the received packet to the start of the output packet transmit.

Mode	Latency
Gig (1000)	880ns
100	1.3us
10	6.5us

### 14.3.2.16 Emulation Control

The emulation control input (EMUSUSP) and submodule emulation control registers allow CPSW\_3G operation to be completely or partially suspended. There are three CPSW\_3G submodules that contain emulation control registers (CPGMAC\_SL1, CPGMAC\_SL2, and CPDMA). The submodule emulation control registers must be accessed to facilitate CPSW\_3G emulation control. The CPSW\_3G module enters the emulation suspend state if all three submodules are configured for emulation suspend and the emulation suspend input is asserted.

A partial emulation suspend state is entered if one or two submodules is configured for emulation suspend and the emulation suspend input is asserted. Emulation suspend occurs at packet boundaries. The emulation control feature is implemented for compatibility with other peripherals.

#### CPGMAC\_SL Emulation Control

The emulation control input (**TBEMUSUP**) and register bits (**soft** and **free** in the **EMControl** register) allow CPGMAC\_SL operation to be suspended. When the emulation suspend state is entered, the CPGMAC\_SL will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For receive, frames that are detected by the CPGMAC\_SL after the suspend state is entered are ignored. Emulation control is implemented for compatibility with other peripherals.

#### CPDMA Emulation Control

The emulation control input (**TBEMUSUP**) and register bits (**soft** and **free** in the **EMControl** register) allow CPDMA operation to be suspended. When the emulation suspend state is entered, the CPDMA will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the tx cell fifo will be transmitted. For receive, frames that are detected by the CPDMA after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Emulation control is implemented for compatibility with other peripherals.

The following table shows the operations of the emulation control input and register bits:

**Table 14-18. Operations of Emulation Control Input and Register Bits**

EMUSUSP	soft	free	Description
0	X	X	Normal Operation
1	0	0	Normal Operation
1	1	0	Emulation Suspend
1	X	1	Normal Operation

### 14.3.2.17 Software IDLE

The submodule software idle register bits enable CPSW\_3G operation to be completely or partially suspended by software control. There are three CPSW\_3G submodules that contain software idle register bits (CPGMAC\_SL1, CPGMAC\_SL2, and CPDMA). Each of the three submodules may be individually commanded to enter the idle state. The idle state is entered at packet boundaries, and no further packet operations will occur on an idled submodule until the idle command is removed. The CPSW\_3G module enters the idle state when all three submodules are commanded to enter and have entered the idle state. Idle status is determined by reading or polling the three submodule idle bits. The CPSW\_3G is in the idle state when all three submodules are in the idle state. The **CPSW\_Soft\_Idle** bit may be set if desired after the submodules are in the idle state. The **CPSW\_Soft\_Idle** bit causes packets to not be transferred from one FIFO to another FIFO internal to the switch.

### 14.3.2.18 Software Reset

The CPSW\_3G software reset register, CPSW\_3GSS software reset register and the three submodule software reset registers enable the CPSW\_3GSS to be reset by software. There are three CPSW\_3G submodules that contain software reset registers (CPGMAC\_SL1, CPGMAC\_SL2, and CPDMA). Each of the three submodules may be individually commanded to be reset by software.

For the CPDMA, the reset state is entered at packet boundaries, at which time the CPDMA reset occurs. The CPGMAC\_SL soft reset is immediate. Submodule reset status is determined by reading or polling the submodule reset bit. If the submodule reset bit is read as a one, then the reset process has not yet completed. The submodule soft reset process could take up to 2ms each. The reset has completed if the submodule reset bit is read as a zero.

After all three submodules (in any order) have been reset and a read of each submodule reset bit indicates that the reset process is complete, the CPSW\_3G software reset register bit may be written to complete the CPSW\_3G module software reset operation. The CPSW\_3G software reset bit controls the reset of the FIFO's, the statistics submodule, and the address lookup engine (ALE). The CPSW\_3G software reset is immediate and will be indicated by reading a zero from the soft reset bit.

The CPSW\_3GSS software reset bit controls the reset of the INT, REGS and CPPI. The CPSW\_3GSS software reset is immediate and will be indicated by reading a zero from the soft reset bit.

#### 14.3.2.19 FIFO Loopback

FIFO loopback mode is entered when the `fifo_loopback` bit in the `CPSW_Control` register is set. FIFO loopback mode causes packets received on a port to be turned around and transmitted back on the same port. Port 0 receive is fixed on channel zero in FIFO loopback mode. The `RXSOFOVERRUN` statistic is incremented for each packet sent in FIFO loopback mode. Packets sent in with errors are returned with errors (they are not dropped). FIFO loopback is intended as a simple mechanism for test purposes. FIFO loopback should be performed in full duplex mode only.

#### 14.3.2.20 CPSW\_3G Network Statistics

The CPSW\_3G has a set of statistics that record events associated with frame traffic on selected switch ports. The statistics values are cleared to zero 38 clocks after the rising edge of `VBUSP_RST_N`. When one or more port enable bits (`stat_port_en[2:0]`) are set, all statistics registers are write to decrement. The value written will be subtracted from the register value with the result being stored in the register. If a value greater than the statistics value is written, then zero will be written to the register (writing `0xffffffff` will clear a statistics location).

When all port enable bits are cleared to zero, all statistics registers are read/write (normal write direct, so writing `0x00000000` will clear a statistics location). All write accesses must be 32-bit accesses. In the below statistics descriptions, "the port" refers to any enabled port (with a corresponding set `stat_port_en[2:0]` bit).

The statistics interrupt (`STAT_PEND`) will be issued if enabled when any statistics value is greater than or equal to `0x80000000`. The statistics interrupt is removed by writing to decrement any statistics value greater than `0x80000000`. The statistics are mapped into internal memory space and are 32-bits wide. All statistics rollover from `0xffffffff` to `0x00000000`.

##### 14.3.2.20.1 Rx-only Statistics Descriptions

###### 14.3.2.20.1.1 Good Rx Frames (Offset = 0h)

The total number of good frames received on the port. A good frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Had a length of 64 to `rx_maxlen` bytes inclusive
- Had no CRC error, alignment error or code error.

See the Rx Align/Code Errors and Rx CRC errors statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

###### 14.3.2.20.1.2 Broadcast Rx Frames (Offset = 4h)

The total number of good broadcast frames received on the port. A good broadcast frame is defined to be:

- Any data or MAC control frame which was destined for only address `0xffffffffffff`

- Had a length of 64 to rx\_maxlen bytes inclusive
- Had no CRC error, alignment error or code error.

See the Rx Align/Code Errors and Rx CRC errors statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

#### 14.3.2.20.1.3 Multicast Rx Frames (Offset = 8h)

The total number of good multicast frames received on the port. A good multicast frame is defined to be:

- Any data or MAC control frame which was destined for any multicast address other than 0xFFFFFFFF
- Had a length of 64 to rx\_maxlen bytes inclusive
- Had no CRC error, alignment error or code error

See the Rx Align/Code Errors and Rx CRC errors statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

#### 14.3.2.20.1.4 Pause Rx Frames (Offset = Ch)

The total number of IEEE 802.3X pause frames received by the port (whether acted upon or not). Such a frame:

- Contained any unicast, broadcast, or multicast address
- Contained the length/type field value 88.08 (hex) and the opcode 0x0001
- Was of length 64 to rx\_maxlen bytes inclusive
- Had no CRC error, alignment error or code error
- Pause-frames had been enabled on the port (tx\_flow\_en = 1).

The port could have been in either half or full-duplex mode.

See the Rx Align/Code Errors and Rx CRC errors statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

#### 14.3.2.20.1.5 Rx CRC Errors (Offset = 10h)

The total number of frames received on the port that experienced a CRC error. Such a frame:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was of length 64 to rx\_maxlen bytes inclusive
- Had no code/align error,
- Had a CRC error

Overruns have no effect upon this statistic.

A CRC error is defined to be:

- A frame containing an even number of nibbles
- Failing the Frame Check Sequence test

#### 14.3.2.20.1.6 Rx Align/Code Errors (Offset = 14h)

The total number of frames received on the port that experienced an alignment error or code error. Such a frame:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was of length 64 to rx\_maxlen bytes inclusive
- Had either an alignment error or a code error

Overruns have no effect upon this statistic.

An alignment error is defined to be:

- A frame containing an odd number of nibbles
- Failing the Frame Check Sequence test if the final nibble is ignored

A code error is defined to be a frame which has been discarded because the port's MRXER pin driven with a one for at least one bit-time's duration at any point during the frame's reception.

Note: RFC 1757 etherStatsCRCAAlignErrors Ref. 1.5 can be calculated by summing Rx Align/Code Errors and Rx CRC errors.

#### **14.3.2.20.1.7 Oversize Rx Frames (Offset = 18h)**

The total number of oversized frames received on the port. An oversized frame is defined to be:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was greater than rx\_maxlen in bytes
- Had no CRC error, alignment error or code error

See the Rx Align/Code Errors and Rx CRC errors statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

#### **14.3.2.20.1.8 Rx Jabbers (Offset = 1Ch)**

The total number of jabber frames received on the port. A jabber frame:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was greater than rx\_maxlen in bytes
- Had no CRC error, alignment error or code error

See the Rx Align/Code Errors and Rx CRC errors statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

#### **14.3.2.20.1.9 Undersize (Short) Rx Frames (Offset = 20h)**

The total number of undersized frames received on the port. An undersized frame is defined to be:

- Was any data frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was greater than rx\_maxlen in bytes
- Had no CRC error, alignment error or code error

See the Rx Align/Code Errors and Rx CRC errors statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

#### **14.3.2.20.1.10 Rx Fragments (Offset = 24h)**

The total number of frame fragments received on the port. A frame fragment is defined to be:

- Any data frame (address matching does not matter)
- Less than 64 bytes long
- Having a CRC error, an alignment error, or a code error
- Not the result of a collision caused by half duplex, collision based flow control

See the Rx Align/Code Errors and Rx CRC errors statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

#### **14.3.2.20.1.11 Rx Start of Frame Overruns (Offset = 84h)**

The total number of frames received on the port that had a CPDMA start of frame (SOF) overrun or were dropped by due to FIFO resource limitations. SOF overrun frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than rx\_maxlen bytes)
- The CPDMA had a start of frame overrun or the packet was dropped due to FIFO resource limitations

#### 14.3.2.20.1.12 Rx Middle of Frame Overruns (Offset = 88h)

The total number of frames received on the port that had a CPDMA middle of frame (MOF) overrun. MOF overrun frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than rx\_maxlen bytes)
- The CPDMA had a middle of frame overrun

#### 14.3.2.20.1.13 Rx DMA Overruns (Offset = 8Ch)

The total number of frames received on the port that had either a DMA start of frame (SOF) overrun or a DMA MOF overrun. An Rx DMA overrun frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than rx\_maxlen bytes)
- The CPGMAC\_SL was unable to receive it because it did not have the DMA buffer resources to receive it (zero head descriptor pointer at the start or during the middle of the frame reception)

CRC errors, alignment errors and code errors have no effect upon this statistic.

#### 14.3.2.20.1.14 Rx Octets (Offset = 30h)

The total number of bytes in all good frames received on the port. A good frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Of length 64 to rx\_maxlen bytes inclusive
- Had no CRC error, alignment error or code error

See the Rx Align/Code Errors and Rx CRC errors statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

#### 14.3.2.20.1.15 Net Octets (Offset = 80h)

The total number of bytes of frame data received and transmitted on the port. Each frame counted:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address (address match does not matter)
- Any length (including less than 64 bytes and greater than rx\_maxlen bytes)

Also counted in this statistic is:

- Every byte transmitted before a carrier-loss was experienced
- Every byte transmitted before each collision was experienced, (i.e. multiple retries are counted each time)
- Every byte received if the port is in half-duplex mode until a jam sequence was transmitted to initiate flow control. (The jam sequence was not counted to prevent double-counting)

Error conditions such as alignment errors, CRC errors, code errors, overruns and underruns do not affect the recording of bytes by this statistic.

The objective of this statistic is to give a reasonable indication of ethernet utilization

### 14.3.2.20.2 Tx-only Statistics Descriptions

The maximum and minimum transmit frame size is software controllable.

#### 14.3.2.20.2.1 Good Tx Frames (Offset = 34h)

The total number of good frames received on the port. A good frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length
- Had no late or excessive collisions, no carrier loss and no underrun

#### 14.3.2.20.2.2 Broadcast Tx Frames (Offset = 38h)

The total number of good broadcast frames received on the port. A good broadcast frame is defined to be:

- Any data or MAC control frame which was destined for only address 0xFFFFFFFF
- Any length
- Had no late or excessive collisions, no carrier loss and no underrun

#### 14.3.2.20.2.3 Multicast Tx Frames (Offset = 3Ch)

The total number of good multicast frames received on the port. A good multicast frame is defined to be:

- Any data or MAC control frame which was destined for any multicast address other than 0xFFFFFFFF
- Any length
- Had no late or excessive collisions, no carrier loss and no underrun

#### 14.3.2.20.2.4 Pause Tx Frames (Offset = 40h)

This statistic indicates the number of IEEE 802.3X pause frames transmitted by the port.

Pause frames cannot underrun or contain a CRC error because they are created in the transmitting MAC, so these error conditions have no effect upon the statistic. Pause frames sent by software will not be included in this count.

Since pause frames are only transmitted in full duplex carrier loss and collisions have no effect upon this statistic.

Transmitted pause frames are always 64 byte multicast frames so will appear in the Tx Multicast Frames and 64octet Frames statistics.

#### 14.3.2.20.2.5 Collisions (Offset = 48h)

This statistic records the total number of times that the port experienced a collision. Collisions occur under two circumstances.

1. When a transmit data or MAC control frame:
  - Was destined for any unicast, broadcast or multicast address
  - Was any size
  - Had no carrier loss and no underrun
  - Experienced a collision. A jam sequence is sent for every non-late collision, so this statistic will increment on each occasion if a frame experiences multiple collisions (and increments on late collisions)

CRC errors have no effect upon this statistic.

2. When the port is in half-duplex mode, flow control is active, and a frame reception begins.

**14.3.2.20.2.6 Single Collision Tx Frames (Offset = 4Ch)**

The total number of frames transmitted on the port that experienced exactly one collision. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced one collision before successful transmission. The collision was not late.

CRC errors have no effect upon this statistic.

**14.3.2.20.2.7 Multiple Collision Tx Frames (Offset = 50h)**

The total number of frames transmitted on the port that experienced multiple collisions. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 2 to 15 collisions before being successfully transmitted. None of the collisions were late.

CRC errors have no effect upon this statistic.

**14.3.2.20.2.8 Excessive Collisions (Offset = 54h)**

The total number of frames for which transmission was abandoned due to excessive collisions. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 16 collisions before abandoning all attempts at transmitting the frame. None of the collisions were late.

CRC errors have no effect upon this statistic.

**14.3.2.20.2.9 Late Collisions (Offset = 58h)**

The total number of frames on the port for which transmission was abandoned because they experienced a late collision. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Experienced a collision later than 512 bit-times into the transmission. There may have been up to 15 previous (non-late) collisions which had previously required the transmission to be re-attempted. The Late Collisions statistic dominates over the single, multiple and excessive Collisions statistics - if a late collision occurs the frame will not be counted in any of these other three statistics.

CRC errors have no effect upon this statistic.

**14.3.2.20.2.10 Tx Underrun (Offset = 5Ch)**

There should be no transmitted frames that experience underrun.

**14.3.2.20.2.11 Deferred Tx Frames (Offset = 44h)**

The total number of frames transmitted on the port that first experienced deferment. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced no collisions before being successfully transmitted

- Found the medium busy when transmission was first attempted, so had to wait.
- CRC errors have no effect upon this statistic.

#### 14.3.2.20.2.12 Carrier Sense Errors (Offset = 60h)

The total number of frames received on the port that had a CPDMA middle of frame (MOF) overrun. MOF overrun frame is defined to be:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- The carrier sense condition was lost or never asserted when transmitting the frame (the frame is not retransmitted). This is a transmit only statistic. Carrier Sense is a don't care for received frames. Transmit frames with carrier sense errors are sent until completion and are not aborted.

CRC errors have no effect upon this statistic.

#### 14.3.2.20.2.13 Tx Octets (Offset = 64h)

The total number of bytes in all good frames transmitted on the port. A good frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Was any size
- Had no late or excessive collisions, no carrier loss and no underrun.

### 14.3.2.20.3 Rx- and Tx-Shared Statistics Descriptions

#### 14.3.2.20.3.1 Rx + Tx 64 Octet Frames (Offset = 68h)

The total number of 64-byte frames received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was exactly 64 bytes long. (If the frame was being transmitted and experienced carrier loss that resulted in a frame of this size being transmitted, then the frame will be recorded in this statistic).

CRC errors, code/align errors and overruns do not affect the recording of frames in this statistic.

#### 14.3.2.20.3.2 Rx + Tx 65–127 Octet Frames (Offset = 6Ch)

The total number of frames of size 65 to 127 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 65 to 127 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

#### 14.3.2.20.3.3 Rx + Tx 128–255 Octet Frames (Offset = 70h)

The total number of frames of size 128 to 255 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 128 to 255 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

**14.3.2.20.3.4 Rx + Tx 256–511 Octet Frames (Offset = 74h)**

The total number of frames of size 256 to 511 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 256 to 511 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

**14.3.2.20.3.5 Rx + Tx 512–1023 Octet Frames (Offset = 78h)**

The total number of frames of size 512 to 1023 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 512 to 1023 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

**14.3.2.20.3.6 Rx + Tx 1024\_ Up Octet Frames (Offset = 7Ch)**

The total number of frames of size 1024 to rx\_maxlen bytes for receive or 1024 up for transmit on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 1024 to rx\_maxlen bytes long on receive, or any size on transmit

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

**Table 14-19. Rx Statistics Summary**

Rx Statistic	Frame/ Oct	Rx/ Rx+T x	Frame Type					Frame Size (bytes)								Event					
			MAC control		Data			<64	64	65- 127	128- 255	256- 511	512- 1023	1024- rx_ maxlen	>rx_ maxle n	Flow Coll.	CRC Error	Align/ Code	Over- run	Addr. Disc.	
			Pause frame	Non- pau se	Multi- cast	Broad- cast	Uni- cast														
Good Rx Frames	F	Rx	(y	y	y	y	y)	n	(y	y	y	y	y	y	y)	n	-	n	n	-	n
Broadcast Rx Frames	F	Rx	(%	%	n	y)	n	n	(y	y	y	y	y	y	y)	n	-	n	n	-	n
Multicast Rx Frames	F	Rx	(%	%	y)	n	n	n	(y	y	y	y	y	y	y)	n	-	n	n	-	n
Pause Rx Frames	F	Rx	y	n	n	n	n	n	(y	y	y	y	y	y	y)	n	-	n	n	-	-
Rx CRC Errors	F	Rx	(y	y	y	y	y)	n	(y	y	y	y	y	y	y)	n	-	y	n	-	n
Rx Align/Code Errors	F	Rx	(y	y	y	y	y)	n	(y	y	y	y	y	y	y)	n	-	-	y	-	n
Oversized Rx Frames	F	Rx	(y	y	y	y	y)	n	n	n	n	n	n	n	y	-	n	n	-	n	
Rx Jabbers	F	Rx	(y	y	y	y	y)	n	n	n	n	n	n	n	y	-	(y	y)	-	n	
Undersized Rx Frames	F	Rx	n	n	(y	y	y)	y	n	n	n	n	n	n	n	-	n	n	-	n	
Rx Fragments	F	Rx	n	n	(y	y	y)	y^	n	n	n	n	n	n	n	-	(y	y)	-	-	
Rx Overruns	F	Rx	(y	y	y	y	y)	(y	y	y	y	y	y	y	y)	-	-	-	y	n	
64octet Frames	F	Rx+T x	(y	y	y	y	y)	n	y	n	n	n	n	n	n	-	-	-	-	n	
65-127octet Frames	F	Rx+T x	(y	y	y	y	y)	n	n	y	n	n	n	n	n	-	-	-	-	n	
128-255octet Frames	F	Rx+T x	(y	y	y	y	y)	n	n		y	n	n	n	n	-	-	-	-	n	
256-511octet Frames	F	Rx+T x	(y	y	y	y	y)	n	n	n	n	y	n	n	n	-	-	-	-	n	
512-1023octet Frames	F	Rx+T x	(y	y	y	y	y)	n	n	n	n	n	y	n	n	-	-	-	-	n	
1024-UPoctet Frames	F	Rx+T x	(y	y	y	y	y)	n	n	n	n	n	n	y	n	-	-	-	-	n	
Rx Octets	O	Rx	(y	y	y	y	y)	n	(y	y	y	y	y	y	y)	n	-	n	n	-	n
Net Octets	O	Rx+T x	(y	y	y	y	y)	(y	y	y	y	y	y	y	y	y)	-	-	-	-	

**Notes for the Rx Statistics Summary:**

1. "AND" is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning "OR" is indicated. Parentheses are significant.
2. "-" indicates conditions which are ignored in the formations of the statistic.
3. Statistics marked "Rx+Tx" are formed by summing the Rx and Tx statistics, each of which is formed independently.
4. The non-pause column refers to all MAC control frames (i.e. frames with length/type=88.08) with opcodes other than 0x0001. The pauseframe column refers to MAC frames with the opcode=0x0001.
5. The multicast, broadcast and unicast columns in the table refer to non-MAC Control/non-pause frames (i.e. data frames).
6. "%" If either a MAC control frame or pause frame has a multicast or broadcast destination address then the appropriate statistics will be updated.
7. "y^" Frame fragments are not counted if less than 8 bytes.
8. flow coll. are half-duplex collisions forced by the MAC to achieve flow-control. A collision will be forced during the first 8 bytes so should not show in frame fragments. Some of the '-'s in this column might in reality be 'n's.
9. The rx\_overruns stat show above is for rx\_mof\_overruns and rx\_sof\_overruns added together.

**Table 14-20. Tx Statistics Summary**

Tx Statistic	Frame/ Oct	Tx/ Rx+ Tx	Frame Type					Frame Size (bytes)							Event									
			MAC control		Data			64	65- 127	128- 255	256- 511	512- 1023	1024 - 1535	> 1535	CRC Error	Collision Type					No Carrier	Que ued	Defe rred	Und er- run
			Pause (MA C)	Any (CP U)	Multi - cast	Broad- cast	Uni- cast									Flow	1	2- 15	16	Late				
Good Tx Frames	F	Tx	(y	y	y	y	y)	(y	y	y	y	y	y	y)	-	-	-	-	n	n	n	-	-	n
Broadcast Tx Frames	F	Tx	n	(%	n	y)	n	(y	y	y	y	y	y	y)	-	-	-	-	n	n	n	-	-	n
Multicast Tx Frames	F	Tx	(y	%	y)	n	n	y	y	y	y	y	y	y)	-	-	-	-	n	n	n	-	-	n
Pause Tx Frames	F	Tx	y	n	n	n	n	y	n	n	n	n	n	n	-	-	-	-	-	-	-	-	-	-
Collisions	F	Tx	n	(y	y	y	y)	(y	y	y	y	y	y	y)	-	(+	+	+	+	+	n	-	-	-
Single Collision Tx Frames	F	Tx	n	(y	y	y	y)	(y	y	y	y	y	y	y)	-	-	y	n	n	n	n	-	-	-
Multiple Collision Tx Frames	F	Tx	n	(y	y	y	y)	(y	y	y	y	y	y	y)	-	-	n	y	n	n	n	-	-	-
Excessive Collisions	F	Tx	n	(y	y	y	y)	(y	y	y	y	y	y	y)	-	-	n	n	y	n	n	-	-	-
Late Collisions	F	Tx	n	(y	y	y	y)	n	(y	y	y	y	y	y)	-	-	-	-	-	y	-	-	-	-
Deferred Tx Frames	F	Tx	n	(y	y	y	y)	(y	y	y	y	y	y	y)	-	-	n	n	n	n	n	-	y	n

**Table 14-20. Tx Statistics Summary (continued)**

Carrier Sense Errors	F	Tx	(y	y	y	y	y)	(y	y	y	y	y	y	y)	-	-	-	-	-	-	y	-	-	-
64octet Frames	F	Rx+ Tx	(y	y	y	y	y)	y	n	n	n	n	n	n	-	-	-	-	n	n	n	-	-	-
65-127octet Frames	F	Rx+ Tx	(y	y	y	y	y)	n	y	n	n	n	n	n	-	-	-	-	n	n	n	-	-	-
128-255octet Frames	F	Rx+ Tx	(y	y	y	y	y)	n	n	y	n	n	n	n	-	-	-	-	n	n	n	-	-	-
256-511octet Frames	F	Rx+ Tx	(y	y	y	y	y)	n	n	n	y	n	n	n	-	-	-	-	n	n	n	-	-	-
512-1023octet Frames	F	Rx+ Tx	(y	y	y	y	y)	n	n	n	n	y	n	n	-	-	-	-	n	n	n	-	-	-
1024-UPoctet Frames	F	Rx+ Tx	(y	y	y	y	y)	n	n	n	n	n	y	y	-	-	-	-	n	n	n	-	-	-
Tx Octets	O	Tx	(y	y	y	y	y)	(y	y	y	y	y	y	y)	-	-	-	-	n	n	n	-	-	n
Net Octets	O	Rx+ Tx	(y	y	y	y	y)	(y	y	y	y	y	y	y)	-	-	\$	\$	\$	\$	\$	-	-	-

**Notes for the Tx Statistics Summary:**

1. "AND" is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning "OR" is indicated. Parentheses are significant.
2. "-" indicates conditions which are ignored in the formations of the statistic.
3. Statistics marked "Rx+Tx" are formed by summing the Rx and Tx statistics, each of which is formed independently.
4. Pause (MAC) frames are issued in the MAC as perfect (no CRC error) 64 byte frames in full duplex only, so they cannot collide.
5. "%" If a CPU sourced MAC control frame has a multicast or broadcast destination address then the appropriate statistics will be updated.
6. "+" indicates collisions which are "summed" (i.e. every collision is counted in the Collisions statistic). Jam sequences used for halfduplex flow control are also counted.
7. "\$" Every byte written on the wire during each retry attempt is also counted in addition to frames which experience no collisions or carrier loss.
8. The flow collision type is for half-duplex collisions forced by the MAC to achieve flow control. Some of the '-'s in this column might in reality be 'n's. To prevent double-counting, Net Octets are unaffected by the jam sequence – the 'received' bytes, however, are counted. (See [Table 14-19](#).)
9. When the transmit Tx FIFO is drained due to the MAC being disabled or link being lost, then the frames being purged will not appear in the Tx statistics.

### 14.3.3 Ethernet Mac Sliver (CPGMAC\_SL)

The CPGMAC\_SL peripheral shall be compliant to the IEEE Std 802.3 Specification. Half duplex mode is supported in 10/100 Mbps mode, but not in 1000 Mbps (gigabit) mode.

Features:

- Synchronous 10/100/1000 Mbit operation.
- G/MII Interface.
- Hardware Error handling including CRC.
- Full Duplex Gigabit operation (half duplex gigabit is not supported).
- EtherStats and 802.3Stats RMON statistics gathering support for external statistics collection module.
- Transmit CRC generation selectable on a per channel basis.
- Emulation Support.
- VLAN Aware Mode Support.
- Hardware flow control.
- Programmable Inter Packet Gap (IPG)

#### 14.3.3.1 GMII/MII Media Independent Interface

The following sections cover operation of the Media Independent Interface in 10/100/1000 Mbps modes. An IEEE 802.3 compliant Ethernet MAC controls the interface.

##### 14.3.3.1.1 Data Reception

###### 14.3.3.1.1.1 Receive Control

Data received from the PHY is interpreted and output. Interpretation involves detection and removal of the preamble and start of frame delimiter, extraction of the address and frame length, data handling, error checking and reporting, cyclic redundancy checking (CRC), and statistics control signal generation.

###### 14.3.3.1.1.2 Receive Inter-Frame Interval

The 802.3 required inter-packet gap (IPG) is 24 GMII clocks (96 bit times) for 10/100 Mbit modes, and 12 GMII clocks (96 bit times) for 1000 Mbit mode. However, the MAC can tolerate a reduced IPG (2 GMII clocks in 10/100 mode and 5 GMII clocks in 1000 mode) with a correct preamble and start frame delimiter.

This interval between frames must comprise (in the following order):

- An Inter-Packet Gap (IPG).
- A seven octet preamble (all octets 0x55).
- A one octet start frame delimiter (0x5D).

###### 14.3.3.1.2 Data Transmission

The Gigabit Ethernet Mac Sliver (GMII) passes data to the PHY when enabled. Data is synchronized to the transmit clock rate. The smallest frame that can be sent is two bytes of data with four bytes of CRC (6 byte frame).

###### 14.3.3.1.2.1 Transmit Control

A jam sequence is output if a collision is detected on a transmit packet. If the collision was late (after the first 64 bytes have been transmitted) the collision is ignored. If the collision is not late, the controller will back off before retrying the frame transmission. When operating in full duplex mode the carrier sense (CRS) and collision sensing modes are disabled.

#### 14.3.3.1.2.2 CRC Insertion

The MAC generates and appends a 32-bit Ethernet CRC onto the transmitted data if the transmit packet header **pass\_crc** bit is zero. For the CPMAC\_SL generated CRC case, a CRC at the end of the input packet data is not allowed.

If the header word **pass\_crc** bit is set, then the last four bytes of the TX data are transmitted as the frame CRC. The four CRC data bytes should be the last four bytes of the frame and should be included in the packet byte count value. The MAC performs no error checking on the outgoing CRC when the **pass\_crc** bit is set.

#### 14.3.3.1.2.3 MTXER

The GMII\_MTXER signal is not used. If an underflow condition occurs on a transmitted frame, the frame CRC will be inverted to indicate the error to the network. Underflow is a hardware error.

#### 14.3.3.1.2.4 Adaptive Performance Optimization (APO)

The Ethernet MAC port incorporates Adaptive Performance Optimization (APO) logic that may be enabled by setting the **tx\_pace** bit in the **MacControl** register. Transmission pacing to enhance performance is enabled when set. Adaptive performance pacing introduces delays into the normal transmission of frames, delaying transmission attempts between stations, reducing the probability of collisions occurring during heavy traffic (as indicated by frame deferrals and collisions) thereby increasing the chance of successful transmission.

When a frame is deferred, suffers a single collision, multiple collisions or excessive collisions, the pacing counter is loaded with an initial value of 31. When a frame is transmitted successfully (without experiencing a deferral, single collision, multiple collision or excessive collision) the pacing counter is decremented by one, down to zero.

With pacing enabled, a new frame is permitted to immediately (after one IPG) attempt transmission only if the pacing counter is zero. If the pacing counter is non zero, the frame is delayed by the pacing delay, a delay of approximately four inter-packet gap delays. APO only affects the IPG preceding the first attempt at transmitting a frame. It does not affect the back-off algorithm for retransmitted frames.

#### 14.3.3.1.2.5 Inter-Packet-Gap Enforcement

The measurement reference for the IPG of 96 bit times is changed depending on frame traffic conditions. If a frame is successfully transmitted without collision, and **MCRS** is de-asserted within approximately 48 bit times of **MTXEN** being de-asserted, then 96 bit times is measured from **MTXEN**. If the frame suffered a collision, or if **MCRS** is not de-asserted until more than approximately 48 bit times after **MTXEN** is de-asserted, then 96 bit times (approximately, but not less) is measured from **MCRS**.

The transmit IPG can be shortened by eight bit times when enabled and triggered. The **tx\_short\_gap\_en** bit in the **MacControl** register enables the **TX\_SHORT\_GAP** input to determine whether the transmit IPG is shortened by eight bit times.

#### 14.3.3.1.2.6 Back Off

The Gigabit Ethernet Mac Sliver (GMII) implements the 802.3 binary exponential back-off algorithm.

#### 14.3.3.1.2.7 Programmable Transmit Inter-Packet Gap

The transmit inter-packet gap (IPG) is programmable through the **Tx\_Gap** register. The default value is decimal 12. The transmit IPG may be increased to the maximum value of 0x1ff. Increasing the IPG is not compatible with transmit pacing. The short gap feature will override the increased gap value, so the short gap feature may not be compatible with an increased IPG.

#### 14.3.3.1.2.8 Speed, Duplex, and Pause Frame Support Negotiation

The CPMAC\_SL can operate in half duplex or full duplex in 10/100 Mbit modes, and can operate in full duplex only in 1000 Mbit mode. Pause frame support is included in 10/100/1000 Mbit modes as configured by the host.

### 14.3.3.2 Frame Classification

Received frames are proper (good) frames if they are between 64 and **rx\_maxlen** in length (inclusive) and contain no errors (code/align/CRC).

Received frames are long frames if their frame count exceeds the value in the **rx\_maxlen** register. The **rx\_maxlen** register reset (default) value is 1518 (dec). Long received frames are either oversized or jabber frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment errors are jabber frames.

Received frames are short frames if their frame count is less than 64 bytes. Short frames that contain no errors are undersized frames. Short frames with CRC, code, or alignment errors are fragment frames.

A received long packet will always contain **rx\_maxlen** number of bytes transferred to memory (if **rx\_cef\_en** = 1). An example with **rx\_maxlen** = 1518 is below:

- If the frame length is 1518, then the packet is not a long packet and there will be 1518 bytes transferred to memory.
- If the frame length is 1519, there will be 1518 bytes transferred to memory. The last three bytes will be the first three CRC bytes.
- If the frame length is 1520, there will be 1518 bytes transferred to memory. The last two bytes will be the first two CRC bytes.
- If the frame length is 1521, there will be 1518 bytes transferred to memory. The last byte will be the first CRC byte.

If the frame length is 1522, there will be 1518 bytes transferred to memory. The last byte will be the last data byte.

### 14.3.4 Command IDLE

The `cmd_idle` bit in the MACCONTROL register allows CPGMAC\_SL operation to be suspended. When the idle state is commanded, the CPGMAC\_SL will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. Received frames that are detected after the suspend state is entered are ignored. Commanded idle is similar in operation to emulation control and clock stop.

### 14.3.5 RMII Interface

The CPRMII peripheral shall be compliant to the RMII specification document.

Features:

- Source Synchronous 10/100 Mbit operation.
- Full and Half Duplex support.

#### 14.3.5.1 RMII Receive (RX)

The CPRMII receive (RX) interface converts the input data from the external RMII PHY (or switch) into the required MII (CPGMAC) signals. The carrier sense and collision signals are determined from the RMII input data stream and transmit inputs as defined in the RMII specification.

An asserted `RMII_RXER` on any di-bit in the received packet will cause an `MII_RXER` assertion to the CPGMAC during the packet. In 10Mbps mode, the error is not required to be duplicated on 10 successive clocks. Any di-bit which has an asserted `RMII_RXER` during any of the 10 replications of the data will cause the error to be propagated.

Any received packet that ends with an improper nibble boundary aligned `RMII_CRS_DV` toggle will issue an `MII_RXER` during the packet to the CPGMAC. Also, a change in speed or duplex mode during packet operations will cause packet corruption.

The CPRMII can accept receive packets with shortened preambles, but 0x55 followed by a 0x5d is the shortest preamble that will be recognized (1 preamble byte with the start of frame byte). At least one byte of preamble with the start of frame indicator is required to begin a packet. An asserted `RMII_CRS_DV` without at least a single correct preamble byte followed by the start of frame indicator will be ignored.

### 14.3.5.2 RMII Transmit (TX)

The CPRMII transmit (TX) interface converts the 3PSW MII input data into the RMII transmit format. The data is then output to the external RMII PHY.

The 3PSW does not source the transmit error (MII TXERR) signal. Any transmit frame from the CPGMAC with an error (ie. underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be deasserted at all times and is not an input into the CPRMII module. Zeroes are output on RMII\_TXD[1:0] for each clock that RMII\_TXEN is deasserted.

### 14.3.6 RGMII Interface

The CPRGMII peripheral shall be compliant to the RGMII specification document.

Features:

- Supports 1000/100/10 Mbps Speed.
- MII mode is not supported.

If RGMII is used, and a 10Mbit operation is desired, in-band mode must be used and an ethernet PHY that supports in-band status signaling must be selected.

#### 14.3.6.1 RGMII Receive (RX)

The CPRGMII receive (RX) interface converts the source synchronous DDR input data from the external RGMII PHY into the required G/MII (CPGMAC) signals.

#### 14.3.6.2 In-Band Mode of Operation

The CPRGMII is operating in the in-band mode of operation when the **RGMIIRX\_INBAND** input is asserted. **RGMIIRX\_INPUT** is asserted by configuring the `ext_en` bit to 1 of the **MACCONTROL** register. The link status, duplexity, and speed are determined from the RGMII input data stream as defined in the RGMII specification. The link speed is indicated as shown in the following table:

RGMIIRX_SPEED(1:0)	Link Speed
00	10 Mbs mode
01	100 Mbs mode
10	1000 Mbs mode
11	reserved

#### 14.3.6.3 Forced Mode of Operation

The CPRGMII is operating in the forced mode of operation when the **RGMIIRX\_INBAND** input is deasserted by setting **MACCONTROL.EXT\_EN** to 0. In the forced mode of operation, the in-band data is ignored if present. In this mode, the contents of **RGMIIRX\_CTL** are meaningless. Link status, duplexity, and speed status should be determined from the external ethernet PHY via MDIO transactions.

#### 14.3.6.4 RGMII Transmit (TX)

The CPRGMII transmit (TX) interface converts the CPGMAC G/MII input data into the DDR RGMII format. The DDR data is then output to the external PHY.

The CPGMAC does not source the transmit error (MTXERR) signal. Any transmit frame from the CPGMAC with an error (ie. underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be deasserted at all times and is not an input into the CPRGMII module.

In 10/100 mode, the **MTXD** (7:0) data bus uses only the lower nibble. The CPRGMII will output the lower nibble twice in 10/100 mode to avoid unnecessary signal switching.

Packets will be precluded from transmission through the CPRGMII module for 4096 transmit clocks after the rising edge of **RGMIIRX\_LINK**. Packet transmission will begin on the first **GMII\_MTXEN** rising edge after the 4096 transmit clock count has expired.

The RGMII0/1\_ID\_MODE bit value in the GMII\_SEL register should only be set to 1 for 'no internal delay'. The device does not support internal delay mode for RGMII.

### 14.3.7 Common Platform Time Sync (CPTS)

The CPTS module is used to facilitate host control of time sync operations. It enables compliance with the IEEE 1588-2008(v2) standard for a precision clock synchronization protocol.

#### 14.3.7.1 Architecture

**Figure 14-10. CPTS Block Diagram**

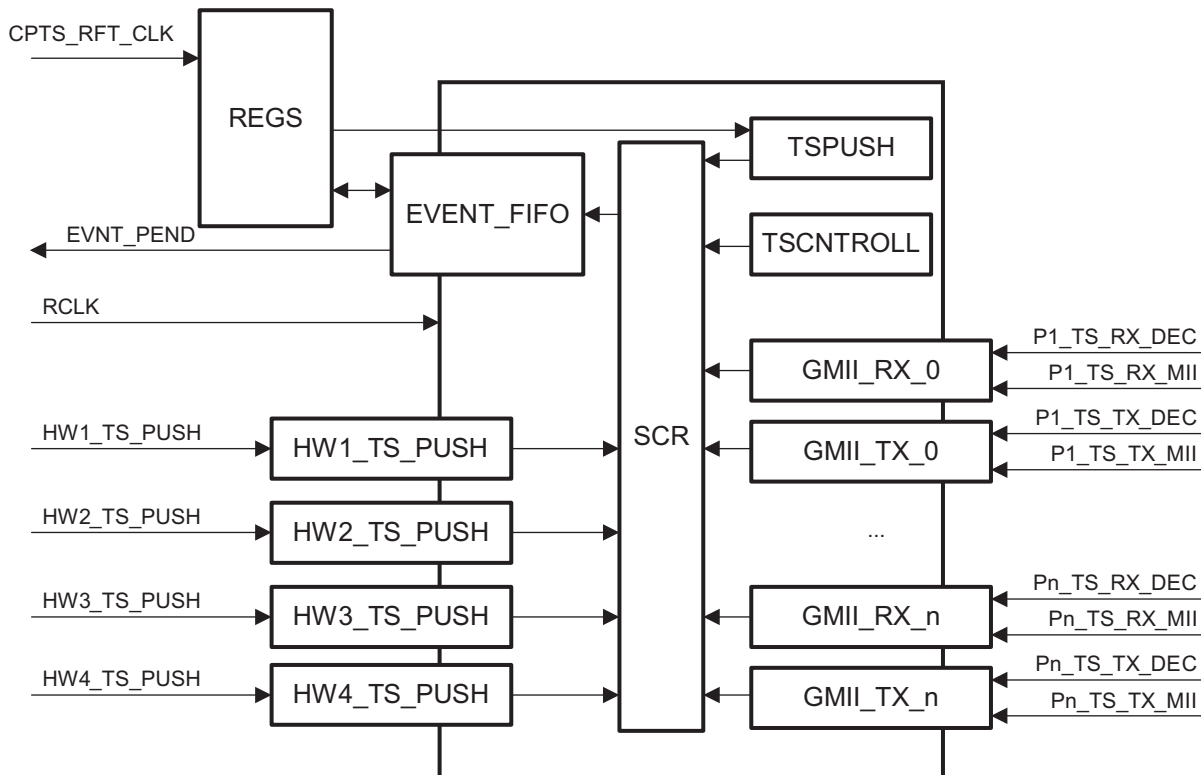

Figure 14-10 shows the architecture of the CPTS module inside the 3PSW Ethernet Subsystem. Time stamp values for every packet transmitted or received on either port of the 3PSW are recorded. At the same time, each packet is decoded to determine if it is a valid time sync event. If so, an event is loaded into the Event FIFO for processing containing the recorded time stamp value when the packet was transmitted or received.

In addition, both hardware (HW<sub>x</sub>\_TS\_PUSH) and software (TS\_PUSH) can be used to read the current time stamp value through the Event FIFO

The reference clock used for the time stamp (RCLK) is sourced from one of the two sources, as shown in Figure 14-10. The source can be selected by configuring the CM\_CPTS\_RFT\_CLKSEL register in the Control Module. For more details, see Chapter 9, *Control Module*.

#### 14.3.7.2 Time Sync Overview

The CPTS module is used to facilitate host control of time sync operations. The CPTS collects time sync events and then presents them to the host for processing. There are five types of time sync events (ethernet receive event, ethernet transmit event, time stamp push event, time stamp rollover event, and time stamp half-rollover event). Each ethernet port can cause transmit and receive events. The time stamp push is initiated by software.

##### 14.3.7.2.1 Time Sync Initialization

The CPTS module should be configured as shown:

- Complete the reset sequence (VBUSP\_RST\_N) to reset the module.

- Write the `rftclk_sel[4:0]` value in the `RFTCLK_Sel` register with the desired reference clock multiplexor value. This value is allowed to be written only when the `cpts_en` bit is cleared to zero.
- Write a one to the `cpts_en` bit in the `TS_Control` register. The RCLK domain is in reset while this bit is low.
- Enable the interrupt by writing a one to the `ts_pend_en` bit in the `TS_Int_Enable` register (if using interrupts and not polling).

#### **14.3.7.2.2 Time Stamp Value**

The time stamp value is a 32-bit value that increments on each RCLK rising edge when `CPTS_EN` is set to one. When `CPTS_EN` is cleared to zero the time stamp value is reset to zero. If more than 32-bits of time stamp are required by the application, the host software must maintain the necessary number of upper bits. The upper time stamp value should be incremented by the host when the rollover event is detected.

For test purposes, the time stamp can be written via the time stamp load function (`CPTS_LOAD_VAL` and `CPTS_LOAD_EN` registers).

#### **14.3.7.2.3 Event FIFO**

All time sync events are pushed onto the Event FIFO. There are 16 locations in the event FIFO with no overrun indication supported. Software must service the event FIFO in a timely manner to prevent FIFO overrun.

#### **14.3.7.2.4 Time Sync Events**

Time Sync events are 64-bit values that are pushed onto the event FIFO and read in two 32-bit reads. `CPTS_EVENT_LOW` and `CPTS_EVENT_HIGH` are defined in [Section 14.5.3.10](#) and [Section 14.5.3.11](#), respectively.

There are six types of sync events

- Time stamp push event
- Hardware time stamp push event
- Time stamp counter rollover event
- Time stamp counter half-rollover event
- Ethernet receive event
- Ethernet transmit event

##### **14.3.7.2.4.1 Time Stamp Push Event**

Software can obtain the current time stamp value (at the time of the write) by initiating a time stamp push event. The push event is initiated by setting the `TS_PUSH` bit of the `CPTS_TS_PUSH` register. The time stamp value is returned in the event, along with a time stamp push event code. Software should not push a second time stamp event on to the FIFO until the first time stamp value has been read from the event FIFO.

##### **14.3.7.2.4.2 Time Stamp Counter Rollover Event**

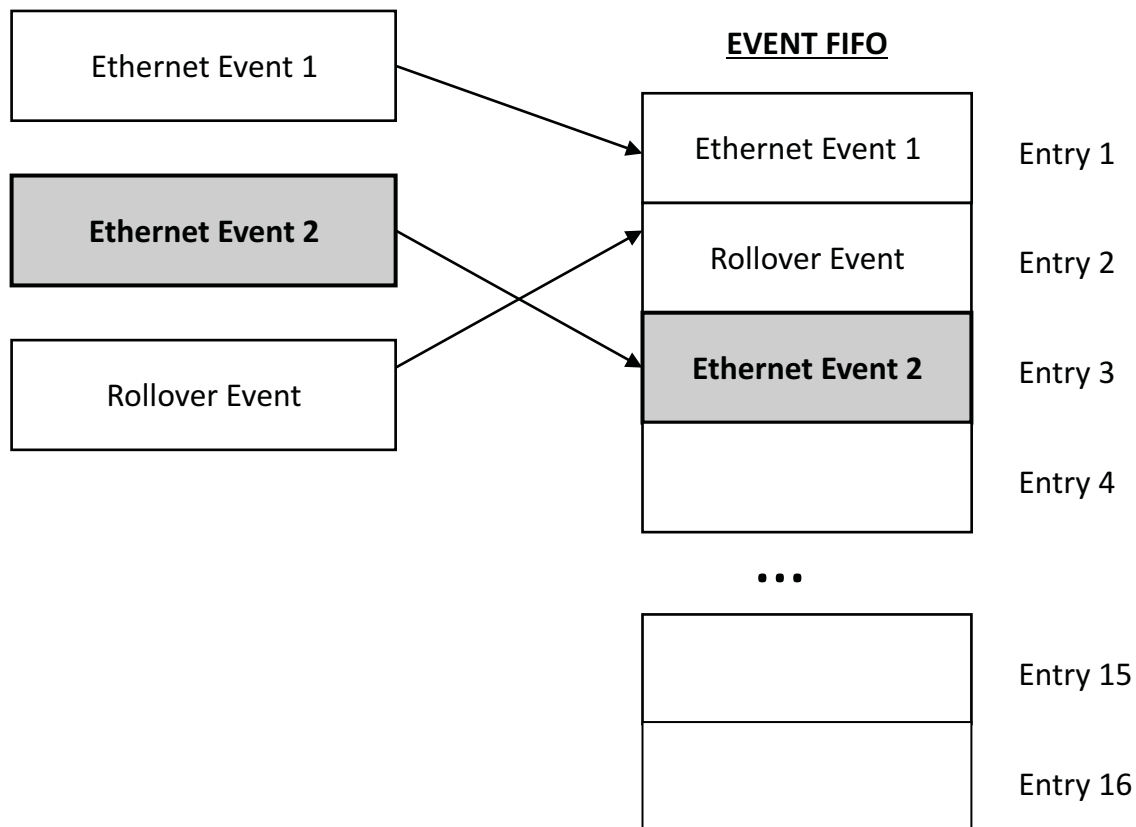

The CPTS module contains a 32-bit time stamp value. The counter upper bits are maintained by host software. The rollover event indicates to software that the time stamp counter has rolled over from `0xFFFF_FFFF` to `0x0000_0000`, and the software maintained upper count value should be incremented.

#### 14.3.7.2.4.3 Time Stamp Counter Half-Rollover Event

The CPTS includes a time stamp counter half-rollover event. The half-rollover event indicates to software that the time stamp value has incremented from 0x7FFF\_FFFF to 0x8000\_0000. The half-rollover event is included to enable software to correct a misaligned event condition. The half-rollover event is included to enable software to determine the correct time for each event that contains a valid time stamp value – such as an Ethernet event. If an Ethernet event occurs around a counter rollover (full rollover), the rollover event could possibly be loaded into the event FIFO before the Ethernet event, even though the Ethernet event time was actually taken before the rollover. Figure 3 below shows a misalignment condition.

This misaligned event condition arises because an ethernet event time stamp occurs at the beginning of a packet and time passes before the packet is determined to be a valid synchronization packet. The misaligned event condition occurs if the rollover occurs in the middle, after the packet time stamp has been taken, but before the packet has been determined to be a valid time sync packet.

**Figure 14-11. Event FIFO Misalignment Condition**

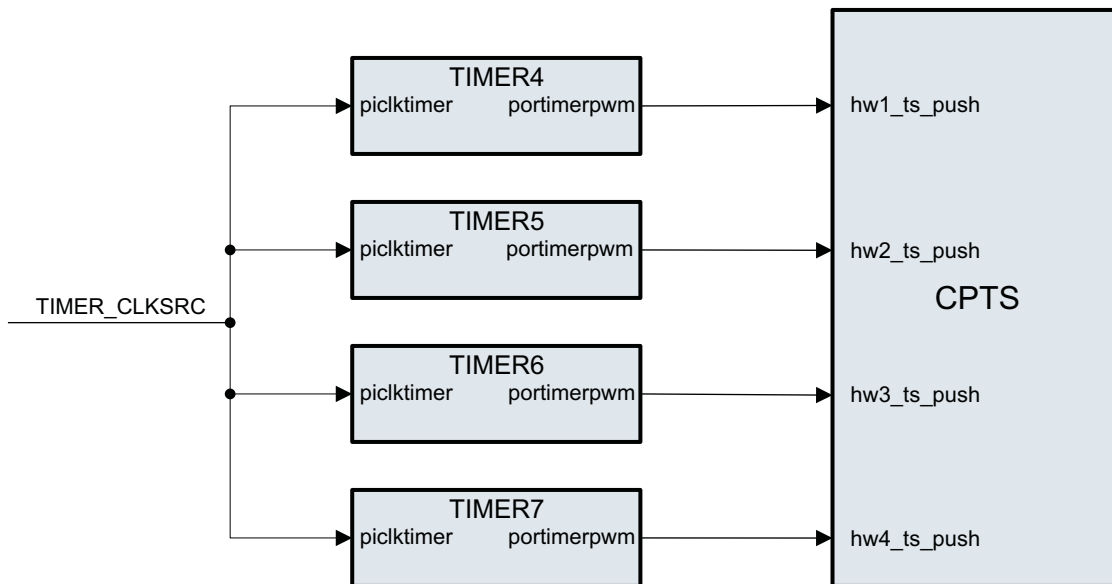

Host software must detect and correct for misaligned event conditions. For every event after a rollover and before a half-rollover, software must examine the time stamp most significant bit. If bit 31 of the time stamp value is low (0x0000\_0000 through 0x7FFF\_FFFF), then the event time stamp was taken after the rollover and no correction is required.

If the value is high (0x8000\_0000 through 0xFFFF\_FFFF), the time stamp value was taken before the rollover and a misalignment is detected. The misaligned case indicates to software that it must subtract one from the upper count value stored in software to calculate the correct time for the misaligned event. The misaligned event occurs only on the rollover boundary and not on the half-rollover boundary. Software only needs to check for misalignment from a rollover event to a half-rollover event.

#### 14.3.7.2.4.4 Hardware Time Stamp Push Event

There are four hardware time stamp inputs (HW1/4\_TS\_PUSH) that can cause hardware time stamp push events to be loaded into the Event FIFO. Each hardware time stamp input is internally connected to the PORTIMERPWM output of each timer as shown in Figure 4.

Figure 14-12. HW1/4\_TSP\_PUSH Connection

The event is loaded into the event FIFO on the rising edge of the timer, and the PORT\_NUMBER field in the EVENT\_HIGH register indicates the hardware time stamp input that caused the event.

Each hardware time stamp input must be asserted for at least 10 periods of the selected RCLK clock. Each input can be enabled or disabled by setting the respective bits in the **CONTROL** register.

Hardware time stamps are intended to be an extremely low frequency signals, such that the event FIFO does not overrun. Software must keep up with the event FIFO and ensure that there is no overrun, or events will be lost.

#### 14.3.7.2.4.5 Ethernet Port Events

##### 14.3.7.2.4.5.1 Ethernet Port Receive Event

Each ethernet port can generate a receive ethernet event. Receive ethernet events are generated for valid received time sync packets. There are two CPTS interfaces for each ethernet receive port. The first is the Px\_TS\_RX\_MII interface and the second is the Px\_TS\_RX\_DEC interface. Information from these interfaces is used to generate an ethernet receive event for each ethernet time sync packet received on the associated port.

The Px\_TS\_RX\_MII interface issues a record signal (pX\_ts\_rx\_mii\_rec) along with a handle (pX\_ts\_rx\_mii\_hndl) for each packet (every packet) that is received on the associated ethernet port. The record signal is a single clock pulse indicating that a receive packet has been detected at the associated port MII interface. The handle value is incremented with each packet and rolls over to zero after 15.

There are 16 possible handle values so there can be a maximum of 16 packets “in flight” from the TS\_RX\_MII to the TS\_RX\_DEC block at any given time. A handle value is reused (not incremented) for any received packet that is shorter than about 31 octets (including preamble). Handle reuse on short packets prevents any possible overrun condition (more than 16 “in flight” packets) if multiple fragments are consecutively received.

Valid receive ethernet time sync events are signaled to the CPTS via the Px\_TS\_RX\_DEC interface. When the pX\_ts\_rx\_dec\_evnt is asserted, a valid event is detected and will be loaded into the event FIFO. Only valid receive time sync packets are indicated on the Px\_TS\_RX\_DEC interface. The pX\_ts\_rx\_dec\_hndl, pX\_ts\_rx\_dec\_msg\_type, and pX\_ts\_rx\_dec\_seq\_id signals are registered on an asserted pX\_ts\_rx\_dec\_evnt. When a Tx\_TS\_RX\_DEC event is asserted, the handle value is used to retrieve the time stamp that was loaded with the same handle value from the Px\_TS\_RX\_MII interface.

#### 14.3.7.2.4.5.2 Ethernet Port Transmit Event

Each ethernet port can generate a transmit ethernet event. Transmit ethernet events are generated for valid transmitted time sync packets. There are two CPTS interfaces for each ethernet transmit port. The first is the Px\_TS\_TX\_DEC interface and the second is the Px\_TS\_TX\_MII interface. Information from these interfaces is used to generate an ethernet transmit event for each ethernet time sync packet transmitted on the associated port.

Valid ethernet transmit time sync events are signaled to the CPTS via the Px\_TS\_TX\_DEC interface. When the pX\_ts\_tx\_dec\_evnt signal is asserted, a valid time sync event has been detected and will be loaded into the event FIFO. Only valid transmit time sync packets are indicated on the Px\_TS\_RX\_DEC interface. The pX\_ts\_tx\_dec\_hndl, pX\_ts\_tx\_dec\_msg\_type, pX\_ts\_tx\_dec\_seq\_id signals are registered on an asserted pX\_ts\_tx\_dec\_evnt.

The time stamp for the event will be generated and signaled from the Px\_TS\_TX\_MII interface when the packet is actually transmitted. The event will be loaded into the event FIFO when the time stamp is recorded as controlled by the Px\_TS\_TX\_MII interface. The handle value is incremented with each time sync event packet and rolls over to zero after 7. There are 8 possible handle values so there can be a maximum of 8 time sync event packets “in flight” from the TS\_TX\_DEC to the TS\_TX\_MII block at any given time. The handle value increments only on time sync event packets.

The Px\_TS\_TX\_MII interface issues a single clock record signal (pX\_ts\_tx\_mii\_rec) at the beginning of each transmitted packet. If the packet is a time sync event packet then a single clock event signal (pX\_ts\_tx\_mii\_evnt) along with a handle (pX\_ts\_tx\_mii\_hndl) will be issued before the next record signal for the next transmitted packet. The event signal will not be issued for packets that were not indicated as valid time sync event packets on the Px\_TS\_TX\_DEC interface. If consecutive record indications occur without an interleaving event indication, then the packet associated with the first record was not a time sync event packet. The record signal is a single clock pulse indicating that a transmit packet egress has been detected at the associated port MII interface.

#### 14.3.7.3 Interrupt Handling

When an event is push onto the Event FIFO, an interrupt can be generated to indicate to software that a time sync event occurred. The following steps should be taken to process time sync events using interrupts:

- Enable the TS\_PEND interrupt by setting the TS\_PEND\_EN bit of the CPTS\_INT\_ENABLE register.
- Upon interrupt, read the CPTS\_EVENT\_LOW and CPTS\_EVENT\_HIGH register values.
- Set the EVENT\_POP field (bit zero) of the CPTS\_EVENT\_POP register to pop the previously read value off of the event FIFO.
- Process the interrupt as required by the application software

Software has the option of processing more than a single event from the event FIFO in the interrupt service routine in the following way:

1. Enable the TS\_PEND interrupt by setting the TS\_PEND\_EN bit of the CPTS\_INT\_ENABLE register.
2. Upon interrupt enter the CPTS service routine.
3. Read the CPTS\_EVENT\_LOW and CPTS\_EVENT\_HIGH register values.
4. Set the EVENT\_POP bit of the CPTS\_EVENT\_POP register to pop the previously read value off of the event FIFO.
5. Wait for an amount of time greater than eight CPTS\_RFT\_CLK periods
6. Read the ts\_pend\_raw bit in the CPTS\_INTSTAT\_RAW register to determine if another valid event is in the event FIFO. If it is asserted then goto step 3. Otherwise goto step 7.
7. Process the interrupt(s) as required by the application software

Software also has the option of disabling the interrupt and polling the ts\_pend\_raw bit of the CPTS\_INTSTAT\_RAW register to determine if a valid event is on the event FIFO.

### 14.3.8 MDIO

The MII Management I/F module implements the 802.3 serial management interface to interrogate and control two Ethernet PHYs simultaneously using a shared two-wire bus. Two user access registers to control and monitor up to two PHYs simultaneously.

#### 14.3.8.1 MII Management Interface Frame Formats

The following tables show the read and write format of the 32-bit MII Management interface frames, respectively.

**Table 14-22. MDIO Read Frame Format**

Preamble	Start Delimiter	Operation Code	PHY Address	Register Address	Turnaround	Data
0xFFFFFFF	01	10	AAAAA	RRRRR	Z0	DDDD.DDDD.DDD D.DDDD

**Table 14-23. MDIO Write Frame Format**

Preamble	Start Delimiter	Operation Code	PHY Address	Register Address	Turnaround	Data
0xFFFFFFF	01	00	AAAAA	RRRRR	10	DDDD.DDDD.DDD D.DDDD

The default or idle state of the two wire serial interface is a logic one. All tri-state drivers should be disabled and the PHY's pull-up resistor will pull the **MDIO** line to a logic one. Prior to initiating any other transaction, the station management entity shall send a preamble sequence of 32 contiguous logic one bits on the **MDIO** line with 32 corresponding cycles on **MDCLK** to provide the PHY with a pattern that it can use to establish synchronization. A PHY shall observe a sequence of 32 contiguous logic one bits on **MDIO** with 32 corresponding **MDCLK** cycles before it responds to any other transaction.

#### Preamble

The start of a frame is indicated by a preamble, which consists of a sequence of 32 contiguous bits all of which are a "1". This sequence provides the PHY a pattern to use to establish synchronization.

#### Start Delimiter

The preamble is followed by the start delimiter which is indicated by a "01" pattern. The pattern assures transitions from the default logic one state to zero and back to one.

#### Operation Code

The operation code for a read is "10", while the operation code for a write is a "00".

#### PHY Address

The PHY address is 5 bits allowing 32 unique values. The first bit transmitted is the MSB of the PHY address.

### Register Address

The Register address is 5 bits allowing 32 registers to be addressed within each PHY. Refer to the 10/100 PHY address map for addresses of individual registers.

### Turnaround

An idle bit time during which no device actively drives the MDIO signal shall be inserted between the register address field and the data field of a read frame in order to avoid contention. During a read frame, the PHY shall drive a zero bit onto MDIO for the first bit time following the idle bit and preceding the Data field. During a write frame, this field shall consist of a one bit followed by a zero bit.

### Data

The Data field is 16 bits. The first bit transmitted and received is the MSB of the data word.

## 14.3.8.2 Functional Description

The MII Management I/F will remain idle until enabled by setting the enable bit in the MDIOControl register. The MII Management I/F will then continuously poll the link status from within the Generic Status Register of all possible 32 PHY addresses in turn recording the results in the MDIOLink register.

The linksel bit in the MDIOUserPhySel register determines the status input that is used. A change in the link status of the two PHYs being monitored will set the appropriate bit in the MDIOLinkIntRaw register and the MDIOLinkIntMasked register, if enabled by the linkint\_enable bit in the MDIOUserPhySel register.

The MDIOAlive register is updated by the MII Management I/F module if the PHY acknowledged the read of the generic status register. In addition, any PHY register read transactions initiated by the host also cause the MDIOAlive register to be updated.

At any time, the host can define a transaction for the MII Management interface module to undertake using the data, phyadr, regadr, and write fields in a MDIOUserAccess register. When the host sets the go bit in this register, the MII Management interface module will begin the transaction without any further intervention from the host. Upon completion, the MII Management interface will clear the go bit and set the userintraw bit in the MDIOUserIntRaw register corresponding to the MDIOUserAccess register being used.

The corresponding bit in the MDIOUserIntMasked register may also be set depending on the mask setting in the MDIOUserIntMaskSet and MDIOUserIntMaskClr registers. A round-robin arbitration scheme is used to schedule transactions which may be queued by the host in different MDIOUserAccess registers. The host should check the status of the go bit in the MDIOUserAccess register before initiating a new transaction to ensure that the previous transaction has completed. The host can use the ack bit in the MDIOUserAccess register to determine the status of a read transaction.

It is necessary for software to use the MII Management interface module to setup the auto-negotiation parameters of each PHY attached to a MAC port, retrieve the negotiation results, and setup the MACControl register in the corresponding MAC.

## 14.4 Software Operation

### 14.4.1 Transmit Operation

After reset the host must write zeroes to all Tx DMA State head descriptor pointers. The Tx port may then be enabled. To initiate packet transmission the host constructs transmit queues in memory (one or more packets for transmission) and then writes the appropriate Tx DMA state head descriptor pointers. For each buffer added to a transmit queue, the host must initialize the Tx buffer descriptor values as follows:

1. Write the Next Descriptor Pointer with the 32-bit aligned address of the next descriptor in the queue (zero if last descriptor).
2. Write the Buffer Pointer with the byte aligned address of the buffer data.
3. Write the Buffer Length with the number of bytes in the buffer.
4. Write the Buffer Offset with the number of bytes in the offset to the data (nonzero with SOP only).
5. Set the SOP, EOP, and Ownership bits as appropriate.
6. Clear the End Of Queue bit.

The port begins Tx packet transmission on a given channel when the host writes the channel's Tx queue head descriptor pointer with the address of the first buffer descriptor in the queue (nonzero value). Each channel may have one or more queues, so each channel may have one or more head descriptor pointers. The first buffer descriptor for each Tx packet must have the Start of Packet (SOP) bit and the Ownership bit set to one by the host. The last buffer descriptor for each Tx packet must have the End of Packet (EOP) bit set to one by the host.

The port will transmit packets until all queued packets have been transmitted and the queue(s) are empty. When each packet transmission is complete, the port will clear the Ownership bit in the packet's SOP buffer descriptor and issue an interrupt to the host by writing the packet's last buffer descriptor address to the queue's Tx DMA State Completion Pointer. The interrupt is generated by the write, regardless of the value written.

When the last packet in a queue has been transmitted, the port sets the End Of Queue bit in the EOP buffer descriptor, clears the Ownership bit in the SOP Descriptor, zeroes the appropriate DMA state head descriptor pointer, and then issues a Tx interrupt to the host by writing to the queue's associated Tx completion pointer (address of the last buffer descriptor processed by the port). The port issues a maskable level interrupt (which may then be routed through external interrupt control logic to the host).

On interrupt from the port, the host processes the buffer queue, detecting transmitted packets by the status of the Ownership bit in the SOP buffer descriptor. If the Ownership bit is cleared to zero, then the packet has been transmitted and the host may reclaim the buffers associated with the packet. The host continues queue processing until the end of the queue or until a SOP buffer descriptor is read that contains a set Ownership bit indicating that the packet transmission is not complete.

The host determines that all packets in the queue have been transmitted when the last packet in the queue has a cleared Ownership bit in the SOP buffer descriptor, the End of Queue bit is set in the last packet EOP buffer descriptor, and the Next Descriptor Pointer of the last packet EOP buffer descriptor is zero. The host acknowledges an interrupt by writing the address of the last buffer descriptor to the queue's associated Tx Completion Pointer in the Tx DMA State.

If the host written buffer address value is different from the buffer address written by the port, then the level interrupt remains asserted. If the host written buffer address value is equal to the port written value, then the level interrupt is deasserted. The port write to the completion pointer actually stores the value in the state register (ram). The host written value is actually not written to the register location. The host written value is compared to the register contents (which was written by the port) and if the two values are equal, the interrupt is removed, otherwise the interrupt remains asserted. The host may process multiple packets previous to acknowledging an interrupt, or the host may acknowledge interrupts for every packet.

A misqueued packet condition may occur when the host adds a packet to a queue for transmission as the port finishes transmitting the previous last packet in the queue. The misqueued packet is detected by the host when queue processing detects a cleared Ownership bit in the SOP buffer descriptor, a set End of Queue bit in the EOP buffer descriptor, and a nonzero Next Descriptor Pointer in the EOP buffer descriptor.

A misqueued packet means that the port read the last EOP buffer descriptor before the host added the new last packet to the queue, so the port determined queue empty just before the last packet was added. The host corrects the misqueued packet condition by initiating a new packet transfer for the misqueued packet by writing the misqueued packet's SOP buffer descriptor address to the appropriate DMA State Tx Queue head Descriptor Pointer.

The host may add packets to the tail end of an active Tx queue at any time by writing the Next Descriptor Pointer to the current last descriptor in the queue. If a Tx queue is empty (inactive), the host may initiate packet transmission at any time by writing the appropriate Tx DMA State head descriptor pointer.

The host software should always check for and reinitiate transmission for misqueued packets during queue processing on interrupt from the port. In order to preclude software underrun, the host should avoid adding buffers to an active queue for any Tx packet that is not complete and ready for transmission.

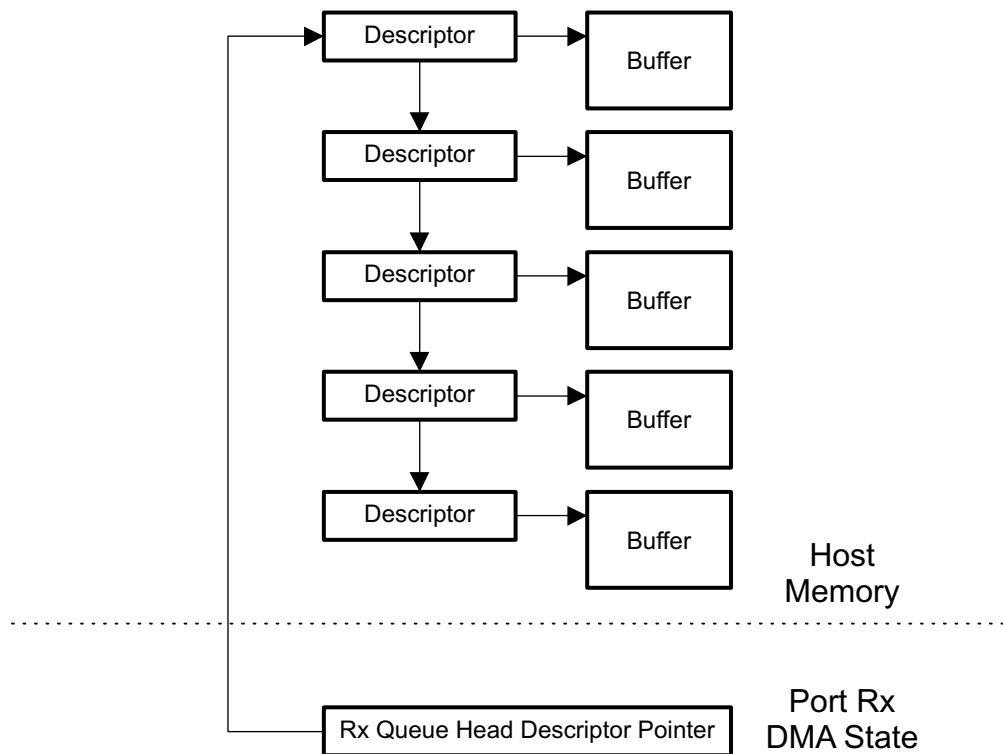

The port determines that a packet is the last packet in the queue by detecting the End of Packet bit set with a zero Next Descriptor Pointer in the packet buffer descriptor. If the End of Packet bit is set and the Next Descriptor Pointer is nonzero, then the queue still contains one or more packets to be transmitted. If the EOP bit is set with a zero Next Descriptor Pointer, then the port will set the EOQ bit in the packet's EOP buffer descriptor and then zero the appropriate head descriptor pointer previous to interrupting the port (by writing the completion pointer) when the packet transmission is complete.

Figure 14-13. Port TX State RAM Entry

### 14.4.2 Receive Operation

Figure 14-14. Port RX DMA State

After reset the host must write zeroes to all Rx DMA State head descriptor pointers. The Rx port may then be enabled. To initiate packet reception, the host constructs receive queues in memory and then writes the appropriate Rx DMA state head descriptor pointer. For each Rx buffer descriptor added to the queue, the host must initialize the Rx buffer descriptor values as follows:

- Write the Next Descriptor Pointer with the 32-bit aligned address of the next descriptor in the queue (zero if last descriptor)
- Write the Buffer Pointer with the byte aligned address of the buffer data
- Clear the Offset field
- Write the Buffer Length with the number of bytes in the buffer
- Clear the SOP, EOP, and EOQ bits
- Set the Ownership bit

The host enables packet reception on a given channel by writing the address of the first buffer descriptor in the queue (nonzero value) to the channel's head descriptor pointer in the channel's Rx DMA state. When packet reception begins on a given channel, the port fills each Rx buffer with data in order starting with the first buffer and proceeding through the Rx queue. If the Buffer Offset in the Rx DMA State is nonzero, then the port will begin writing data after the offset number of bytes in the SOP buffer. The port performs the following operations at the end of each packet reception:

- Overwrite the buffer length in the packet's EOP buffer descriptor with the number of bytes actually received in the packet's last buffer. The host initialized value is the buffer size. The overwritten value will be less than or equal to the host initialized value.
- Set the EOP bit in the packet's EOP buffer descriptor.
- Set the EOQ bit in the packet's EOP buffer descriptor if the current packet is the last packet in the queue.
- Overwrite the packet's SOP buffer descriptor Buffer Offset with the Rx DMA state value (the host initialized the buffer descriptor Buffer Offset value to zero). All non SOP buffer descriptors must have a zero Buffer Offset initialized by the host.

- Overwrite the packet's SOP buffer descriptor buffer length with the number of valid data bytes in the buffer. If the buffer is filled up, the buffer length will be the buffer size minus buffer offset.
- Set the SOP bit in the packet's SOP buffer descriptor.
- Write the SOP buffer descriptor Packet Length field.
- Clear the Ownership bit in the packet's SOP buffer descriptor.
- Issue an Rx host interrupt by writing the address of the packet's last buffer descriptor to the queue's Rx DMA State Completion Pointer. The interrupt is generated by the write to the Rx DMA State Completion Pointer address location, regardless of the value written.

On interrupt the host processes the Rx buffer queue detecting received packets by the status of the Ownership bit in each packet's SOP buffer descriptor. If the Ownership bit is cleared then the packet has been completely received and is available to be processed by the host.

The host may continue Rx queue processing until the end of the queue or until a buffer descriptor is read that contains a set Ownership bit indicating that the next packet's reception is not complete. The host determines that the Rx queue is empty when the last packet in the queue has a cleared Ownership bit in the SOP buffer descriptor, a set End of Queue bit in the EOP buffer descriptor, and the Next Descriptor Pointer in the EOP buffer descriptor is zero.

A misqueued buffer may occur when the host adds buffers to a queue as the port finishes the reception of the previous last packet in the queue. The misqueued buffer is detected by the host when queue processing detects a cleared Ownership bit in the SOP buffer descriptor, a set End of Queue bit in the EOP buffer descriptor, and a nonzero Next Descriptor Pointer in the EOP buffer descriptor.

A misqueued buffer means that the port read the last EOP buffer descriptor before the host added buffer descriptor(s) to the queue, so the port determined queue empty just before the host added more buffer descriptor(s). In the transmit case, the packet transmission is delayed by the time required for the host to determine the condition and reinitiate the transaction, but the packet is not actually lost. In the receive case, receive overrun condition may occur in the misqueued buffer case.

If a new packet reception is begun during the time that the port has determined the end of queue condition, then the received packet will overrun (start of packet overrun). If the misqueued buffer occurs during the middle of a packet reception then middle of packet overrun may occur. If the misqueued buffer occurs after the last packet has completed, and is corrected before the next packet reception begins, then overrun will not occur. The host acts on the misqueued buffer condition by writing the added buffer descriptor address to the appropriate Rx DMA State Head Descriptor Pointer.

### 14.4.3 Initializing the MDIO Module

The following steps are performed by the application software or device driver to initialize the MDIO device:

1. Configure the PREAMBLE and CLKDIV bits in the MDIO control register (MDIOCONTROL).
  2. Enable the MDIO module by setting the ENABLE bit in MDIOCONTROL.
  3. The MDIO PHY alive status register (MDIOALIVE) can be read in polling fashion until a PHY connected to the system responded, and the MDIO PHY link status register (MDIOLINK) can determine whether this PHY already has a link.
  4. Setup the appropriate PHY addresses in the MDIO user PHY select register (MDIOUSERPHYSEL<sub>n</sub>), and set the LINKINTENB bit to enable a link change event interrupt if desirable.
- If an interrupt on general MDIO register access is desired, set the corresponding bit in the MDIO user command complete interrupt mask set register (MDIOUSERINTMASKSET) to use the MDIO user access register (MDIOUSERACCESS<sub>n</sub>). Since only one PHY is used in this device, the application software can use one MDIOUSERACCESS<sub>n</sub> to trigger a completion interrupt; the other MDIOUSERACCESS<sub>n</sub> is not setup.

### 14.4.4 Writing Data to a PHY Register

The MDIO module includes a user access register (MDIOUSERACCESS<sub>n</sub>) to directly access a specified PHY device. To write a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (MDIOUSERACCESS<sub>n</sub>) is cleared.

2. Write to the GO, WRITE, REGADR, PHYADR, and DATA bits in MDIOUSERACCESS $n$  corresponding to the PHY and PHY register you want to write.
3. The write operation to the PHY is scheduled and completed by the MDIO module. Completion of the write operation can be determined by polling the GO bit in MDIOUSERACCESS $n$  for a 0.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (MDIOUSERINTRAW) corresponding to USERACCESS $n$  used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (MDIOUSERINTMASKSET), then the bit is also set in the MDIO user command complete interrupt register (MDIOUSERINTMASKED) and an interrupt is triggered on the CPU.

#### 14.4.5 Reading Data from a PHY Register

The MDIO module includes a user access register (MDIOUSERACCESS $n$ ) to directly access a specified PHY device. To read a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (MDIOUSERACCESS $n$ ) is cleared.
2. Write to the GO, REGADR, and PHYADR bits in MDIOUSERACCESS $n$  corresponding to the PHY and PHY register you want to read.
3. The read data value is available in the DATA bits in MDIOUSERACCESS $n$  after the module completes the read operation on the serial bus. Completion of the read operation can be determined by polling the GO and ACK bits in MDIOUSERACCESS $n$ . After the GO bit has cleared, the ACK bit is set on a successful read.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (MDIOUSERINTRAW) corresponding to USERACCESS $n$  used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (MDIOUSERINTMASKSET), then the bit is also set in the MDIO user command complete interrupt register (MDIOUSERINTMASKED) and an interrupt is triggered on the CPU.

#### 14.4.6 Initialization and Configuration of CPSW

To configure the 3PSW Ethernet Subsystem for operation the host must perform the following:

- Select the Interface (GMII/RGMII/MII) Mode in the Control Module.
- Configure pads (PIN muxing) as per the Interface Selected using the appropriate pin muxing conf\_XXX registers in the Control Module.
- Enable the 3PSW Ethernet Subsystem Clocks. See [Section 14.2.2](#) and [Section 8.1](#) to enable the appropriate clocks.
- Configure the PRCM Registers CM\_PER\_CPSW\_CLKSTCTRL and CM\_PER\_CPSW\_CLKSTCTRL to enable power and clocks to the 3PSW Ethernet Subsystem. See [Section 8.1](#) for register details.
- Apply soft reset to 3PSW Subsystem, CPSW\_3G, CPGMAC\_SL1/2, and CPDMA (see the soft reset registers in the following sections).
- Initialize the HDPs (Header Description Pointer) and CPs (Completion Pointer) to NULL
- Configure the Interrupts (see [Chapter 6](#)).
- Configure the CPSW\_3G Control register.
- Configure the Statistics Port Enable register
- Configure the ALE. (See [Section 14.3.2.7](#).)
- Configure the MDIO.
- Configure the CPDMA receive DMA controller.
- Configure the CPDMA transmit DMA controller.
- Configure the CPPI Tx and Rx Descriptors.
- Configure CPGMAC\_SL1 and CPGMAC\_SL2 as per the desired mode of operations.
- Start up RX and TX DMA (write to HDP of Rx and Tx).
- Wait for the completion of the transfer (HDP cleared to zero).

## 14.5 Ethernet Subsystem Registers

### 14.5.1 CPSW\_ALE Registers

Table 14-24 lists the memory-mapped registers for the CPSW\_ALE. All register offset addresses not listed in Table 14-24 should be considered as reserved locations and the register contents should not be modified.

**Table 14-24. CPSW\_ALE REGISTERS**

Offset	Acronym	Register Name	Section
0h	IDVER	ADDRESS LOOKUP ENGINE ID/VERSION REGISTER	<a href="#">Section 14.5.1.1</a>
8h	CONTROL	ADDRESS LOOKUP ENGINE CONTROL REGISTER	<a href="#">Section 14.5.1.2</a>

R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-26. CONTROL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	ENABLE_ALE	R/W-0	0	Enable ALE - 0 - Drop all packets 1 - Enable ALE packet processing
30	CLEAR_TABLE	R/W-0	0	Clear ALE address table - Setting this bit causes the ALE hardware to write all table bit values to zero. Software must perform a clear table operation as part of the ALE setup/configuration process. Setting this bit causes all ALE accesses to be held up for 64 clocks while the clear is performed. Access to all ALE registers will be blocked (wait states) until the 64 clocks have completed. This bit cannot be read as one because the read is blocked until the clear table is completed at which time this bit is cleared to zero.
29	AGE_OUT_NOW	R/W-0	0	Age Out Address Table Now - Setting this bit causes the ALE hardware to remove (free up) any ageable table entry that does not have a set touch bit. This bit is cleared when the age out process has completed. This bit may be read. The age out process takes 4096 clocks best case (no ale packet processing during ageout) and 66550 clocks absolute worst case.
8	EN_P0_UNI_FLOOD	R/W-0	0	Enable Port 0 (Host Port) unicast flood 0 - do not flood unknown unicast packets to host port (p0) 1 - flood unknown unicast packets to host port (p0)
7	LEARN_NO_VID	R/W-0	0	Learn No VID - 0 - VID is learned with the source address 1 - VID is not learned with the source address (source address is not tied to VID).
6	EN_VID0_MODE	R/W-0	0	Enable VLAN ID = 0 Mode 0 - Process the packet with VID = PORT_VLAN[11:0]. 1 - Process the packet with VID = 0.
5	ENABLE_OUI_DENY	R/W-0	0	Enable OUI Deny Mode - When set this bit indicates that a packet with a non OUI table entry matching source address will be dropped to the host unless the destination address matches a multicast table entry with the super bit set.
4	BYPASS	R/W-0	0	ALE Bypass - When set, all packets received on ports 0 and 1 are sent to the host (only to the host).

**Table 14-26. CONTROL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3	RATE_LIMIT_TX	R/W-0	0	Rate Limit Transmit mode - 0 - Broadcast and multicast rate limit counters are received port based 1 - Broadcast and multicast rate limit counters are transmit port based.
2	VLAN_AWARE	R/W-0	0	ALE VLAN Aware - Determines what is done if VLAN not found. 0 - Flood if VLAN not found 1 - Drop packet if VLAN not found
1	ENABLE_AUTH_MODE	R/W-0	0	Enable MAC Authorization Mode - Mac authorization mode requires that all table entries be made by the host software. There are no learned address in authorization mode and the packet will be dropped if the source address is not found (and the destination address is not a multicast address with the super table entry bit set). 0 - The ALE is not in MAC authorization mode 1 - The ALE is in MAC authorization mode
0	ENABLE_RATE_LIMIT	R/W-0	0	Enable Broadcast and Multicast Rate Limit 0 - Broadcast/Multicast rates not limited 1 - Broadcast/Multicast packet reception limited to the port control register rate limit fields.

### 14.5.1.3 PRESCALE Register (offset = 10h) [reset = 0h]

PRESCALE is shown in [Figure 14-17](#) and described in [Table 14-27](#).

ADDRESS LOOKUP ENGINE PRESCALE REGISTER

**Figure 14-17. PRESCALE Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-27. PRESCALE Register Field Descriptions**

Bit	Field	Type	Reset	Description
19-0	PRESCALE	R/W-0	0	ALE Prescale Register - The input clock is divided by this value for use in the multicast/broadcast rate limiters. The minimum operating value is 0x10. The prescaler is off when the value is zero.

#### 14.5.1.4 UNKNOWN\_VLAN Register (offset = 18h) [reset = 0h]

UNKNOWN\_VLAN is shown in [Figure 14-18](#) and described in [Table 14-28](#).

ADDRESS LOOKUP ENGINE UNKNOWN VLAN REGISTER

**Figure 14-18. UNKNOWN\_VLAN Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-28. UNKNOWN\_VLAN Register Field Descriptions**

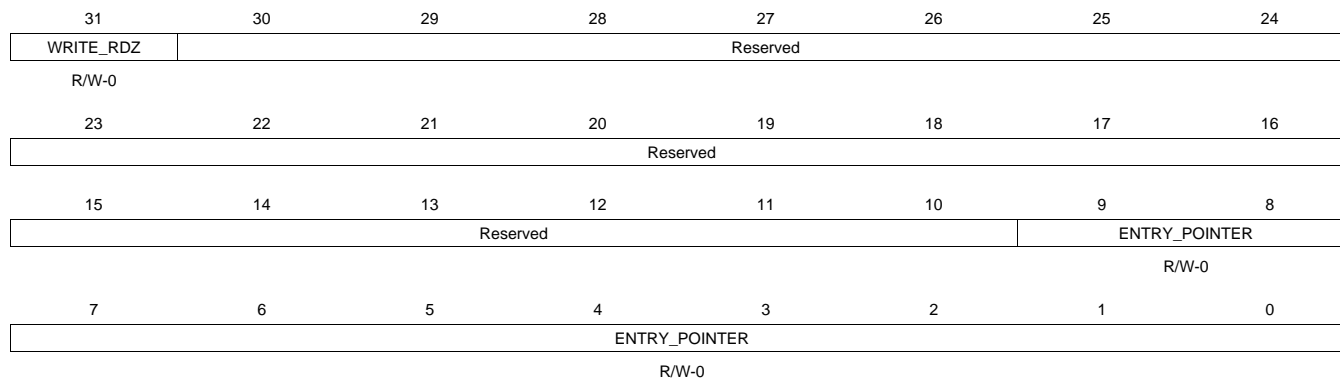

Bit	Field	Type	Reset	Description
29-24	UNKNOWN_FORCE_UNTAGGED_EGRESS	R/W-0	0	Unknown VLAN Force Untagged Egress.
21-16	UNKNOWN_REG_MCAST_FLOOD_MASK	R/W-0	0	Unknown VLAN Registered Multicast Flood Mask
13-8	UNKNOWN_MCAST_FLOOD_MASK	R/W-0	0	Unknown VLAN Multicast Flood Mask
5-0	UNKNOWN_VLAN_MEMBER_LIST	R/W-0	0	Unknown VLAN Member List

### 14.5.1.5 TBLCTL Register (offset = 20h) [reset = 0h]

TBLCTL is shown in [Figure 14-19](#) and described in [Table 14-29](#).

ADDRESS LOOKUP ENGINE TABLE CONTROL

**Figure 14-19. TBLCTL Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-29. TBLCTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	WRITE_RDZ	R/W-0	0	Write Bit - This bit is always read as zero. Writing a 1 to this bit causes the three table word register values to be written to the entry_pointer location in the address table. Writing a 0 to this bit causes the three table word register values to be loaded from the entry_pointer location in the address table so that they may be subsequently read. A read of any ALE address location will be stalled until the read or write has completed.
9-0	ENTRY_POINTER	R/W-0	0	Table Entry Pointer - The entry_pointer contains the table entry value that will be read/written with accesses to the table word registers.

**14.5.1.6 TBLW2 Register (offset = 34h) [reset = 0h]**

TBLW2 is shown in [Figure 14-20](#) and described in [Table 14-30](#).

ADDRESS LOOKUP ENGINE TABLE WORD 2 REGISTER

**Figure 14-20. TBLW2 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-30. TBLW2 Register Field Descriptions**

Bit	Field	Type	Reset	Description
7-0	ENTRY71-64	R/W-0	0	Table entry bits 71:64

### 14.5.1.7 TBLW1 Register (offset = 38h) [reset = 0h]

TBLW1 is shown in [Figure 14-21](#) and described in [Table 14-31](#).

ADDRESS LOOKUP ENGINE TABLE WORD 1 REGISTER

**Figure 14-21. TBLW1 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-31. TBLW1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	ENTRY63_32	R/W	0h	Table entry bits 63:32

**14.5.1.8 TBLW0 Register (offset = 3Ch) [reset = 0h]**

TBLW0 is shown in [Figure 14-22](#) and described in [Table 14-32](#).

ADDRESS LOOKUP ENGINE TABLE WORD 0 REGISTER

**Figure 14-22. TBLW0 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-32. TBLW0 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	ENTRY31_0	R/W	0h	Table entry bits 31:0

**14.5.1.9 PORTCTL0 Register (offset = 40h) [reset = 0h]**

 PORTCTL0 is shown in [Figure 14-23](#) and described in [Table 14-33](#).

**ADDRESS LOOKUP ENGINE PORT 0 CONTROL REGISTER**
**Figure 14-23. PORTCTL0 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-33. PORTCTL0 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	BCAST_LIMIT	R/W-0	0	Broadcast Packet Rate Limit - Each prescale pulse loads this field into the port broadcast rate limit counter. The port counters are decremented with each packet received or transmitted depending on whether the mode is transmit or receive. If the counters decrement to zero, then further packets are rate limited until the next prescale pulse. Broadcast rate limiting is enabled by a non-zero value in this field
23-16	MCAST_LIMIT	R/W-0	0	Multicast Packet Rate Limit - Each prescale pulse loads this field into the port multicast rate limit counter. The port counters are decremented with each packet received or transmitted depending on whether the mode is transmit or receive. If the counters decrement to zero, then further packets are rate limited until the next prescale pulse. Multicast rate limiting is enabled by a non-zero value in this field.
5	NO_SA_UPDATE	R/W-0	0	No Source Address Update - When set the port is disabled from updating the source port number in an ALE table entry.
4	NO_LEARN	R/W-0	0	No Learn Mode - When set the port is disabled from learning an address.
3	VID_INGRESS_CHECK	R/W-0	0	VLAN ID Ingress Check - If VLAN not found then drop the packet. Packets with an unknown (default) VLAN will be dropped.
2	DROP_UNTAGGED	R/W-0	0	Drop Untagged Packets - Drop non-VLAN tagged ingress packets.
1-0	PORT_STATE	R/W-0	0	Port State 0 - Disabled 1 - Blocked 2 - Learn 3 - Forward

**14.5.1.10 PORTCTL1 Register (offset = 44h) [reset = 0h]**

PORTCTL1 is shown in [Figure 14-24](#) and described in [Table 14-34](#).

**ADDRESS LOOKUP ENGINE PORT 1 CONTROL REGISTER**
**Figure 14-24. PORTCTL1 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-34. PORTCTL1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	BCAST_LIMIT	R/W-0	0	Broadcast Packet Rate Limit - Each prescale pulse loads this field into the port broadcast rate limit counter. The port counters are decremented with each packet received or transmitted depending on whether the mode is transmit or receive. If the counters decrement to zero, then further packets are rate limited until the next prescale pulse. Broadcast rate limiting is enabled by a non-zero value in this field
23-16	MCAST_LIMIT	R/W-0	0	Multicast Packet Rate Limit - Each prescale pulse loads this field into the port multicast rate limit counter. The port counters are decremented with each packet received or transmitted depending on whether the mode is transmit or receive. If the counters decrement to zero, then further packets are rate limited until the next prescale pulse. Multicast rate limiting is enabled by a non-zero value in this field.
5	NO_SA_UPDATE	R/W-0	0	No Source Address Update - When set the port is disabled from updating the source port number in an ALE table entry.
4	NO_LEARN	R/W-0	0	No Learn Mode - When set the port is disabled from learning an address.
3	VID_INGRESS_CHECK	R/W-0	0	VLAN ID Ingress Check - If VLAN not found then drop the packet. Packets with an unknown (default) VLAN will be dropped.
2	DROP_UNTAGGED	R/W-0	0	Drop Untagged Packets - Drop non-VLAN tagged ingress packets.
1-0	PORT_STATE	R/W-0	0	Port State 0 - Disabled 1 - Blocked 2 - Learn 3 - Forward

**14.5.1.11 PORTCTL2 Register (offset = 48h) [reset = 0h]**

 PORTCTL2 is shown in [Figure 14-25](#) and described in [Table 14-35](#).

**ADDRESS LOOKUP ENGINE PORT 2 CONTROL REGISTER**
**Figure 14-25. PORTCTL2 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-35. PORTCTL2 Register Field Descriptions**

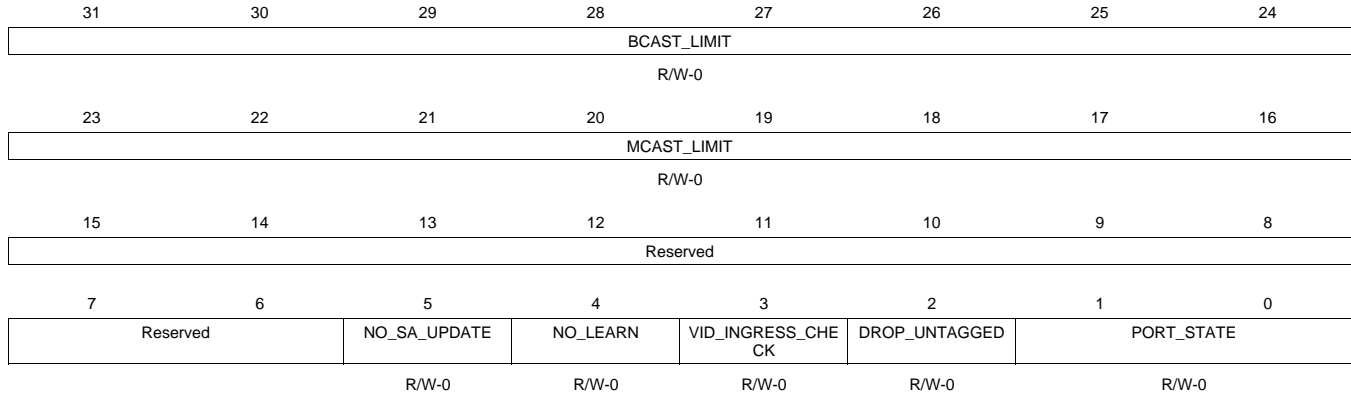

Bit	Field	Type	Reset	Description
31-24	BCAST_LIMIT	R/W-0	0	Broadcast Packet Rate Limit - Each prescale pulse loads this field into the port broadcast rate limit counter. The port counters are decremented with each packet received or transmitted depending on whether the mode is transmit or receive. If the counters decrement to zero, then further packets are rate limited until the next prescale pulse. Broadcast rate limiting is enabled by a non-zero value in this field
23-16	MCAST_LIMIT	R/W-0	0	Multicast Packet Rate Limit - Each prescale pulse loads this field into the port multicast rate limit counter. The port counters are decremented with each packet received or transmitted depending on whether the mode is transmit or receive. If the counters decrement to zero, then further packets are rate limited until the next prescale pulse. Multicast rate limiting is enabled by a non-zero value in this field.
5	NO_SA_UPDATE	R/W-0	0	No Source Address Update - When set the port is disabled from updating the source port number in an ALE table entry.
4	NO_LEARN	R/W-0	0	No Learn Mode - When set the port is disabled from learning an address.
3	VID_INGRESS_CHECK	R/W-0	0	VLAN ID Ingress Check - If VLAN not found then drop the packet. Packets with an unknown (default) VLAN will be dropped.
2	DROP_UNTAGGED	R/W-0	0	Drop Untagged Packets - Drop non-VLAN tagged ingress packets.
1-0	PORT_STATE	R/W-0	0	Port State 0 - Disabled 1 - Blocked 2 - Learn 3 - Forward

**14.5.1.12 PORTCTL3 Register (offset = 4Ch) [reset = 0h]**

PORTCTL3 is shown in [Figure 14-26](#) and described in [Table 14-36](#).

**ADDRESS LOOKUP ENGINE PORT 3 CONTROL REGISTER**

**Figure 14-26. PORTCTL3 Register**

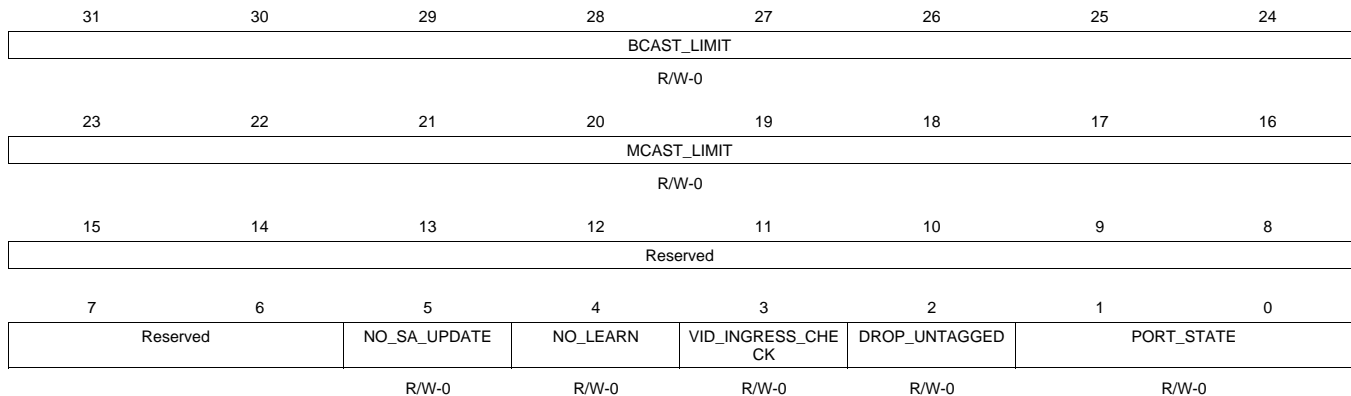

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-36. PORTCTL3 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	BCAST_LIMIT	R/W-0	0	Broadcast Packet Rate Limit - Each prescale pulse loads this field into the port broadcast rate limit counter. The port counters are decremented with each packet received or transmitted depending on whether the mode is transmit or receive. If the counters decrement to zero, then further packets are rate limited until the next prescale pulse. Broadcast rate limiting is enabled by a non-zero value in this field
23-16	MCAST_LIMIT	R/W-0	0	Multicast Packet Rate Limit - Each prescale pulse loads this field into the port multicast rate limit counter. The port counters are decremented with each packet received or transmitted depending on whether the mode is transmit or receive. If the counters decrement to zero, then further packets are rate limited until the next prescale pulse. Multicast rate limiting is enabled by a non-zero value in this field.
5	NO_SA_UPDATE	R/W-0	0	No Source Address Update - When set the port is disabled from updating the source port number in an ALE table entry.
4	NO_LEARN	R/W-0	0	No Learn Mode - When set the port is disabled from learning an address.
3	VID_INGRESS_CHECK	R/W-0	0	VLAN ID Ingress Check - If VLAN not found then drop the packet. Packets with an unknown (default) VLAN will be dropped.
2	DROP_UNTAGGED	R/W-0	0	Drop Untagged Packets - Drop non-VLAN tagged ingress packets.
1-0	PORT_STATE	R/W-0	0	Port State 0 - Disabled 1 - Blocked 2 - Learn 3 - Forward

**14.5.1.13 PORTCTL4 Register (offset = 50h) [reset = 0h]**

 PORTCTL4 is shown in [Figure 14-27](#) and described in [Table 14-37](#).

**ADDRESS LOOKUP ENGINE PORT 4 CONTROL REGISTER**
**Figure 14-27. PORTCTL4 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-37. PORTCTL4 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	BCAST_LIMIT	R/W-0	0	Broadcast Packet Rate Limit - Each prescale pulse loads this field into the port broadcast rate limit counter. The port counters are decremented with each packet received or transmitted depending on whether the mode is transmit or receive. If the counters decrement to zero, then further packets are rate limited until the next prescale pulse. Broadcast rate limiting is enabled by a non-zero value in this field
23-16	MCAST_LIMIT	R/W-0	0	Multicast Packet Rate Limit - Each prescale pulse loads this field into the port multicast rate limit counter. The port counters are decremented with each packet received or transmitted depending on whether the mode is transmit or receive. If the counters decrement to zero, then further packets are rate limited until the next prescale pulse. Multicast rate limiting is enabled by a non-zero value in this field.
5	NO_SA_UPDATE	R/W-0	0	No Source Address Update - When set the port is disabled from updating the source port number in an ALE table entry.
4	NO_LEARN	R/W-0	0	No Learn Mode - When set the port is disabled from learning an address.
3	VID_INGRESS_CHECK	R/W-0	0	VLAN ID Ingress Check - If VLAN not found then drop the packet. Packets with an unknown (default) VLAN will be dropped.

**14.5.2.1 TX\_IDVER Register (offset = 0h) [reset = 180108h]**

 TX\_IDVER is shown in [Figure 14-29](#) and described in [Table 14-40](#).

CPDMA\_REGS TX IDENTIFICATION AND VERSION REGISTER

**Figure 14-29. TX\_IDVER Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-40. TX\_IDVER Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	TX_IDENT	R	18h	TX Identification Value
15-8	TX_MAJOR_VER	R	1h	TX Major Version Value - The value read is the major version number
7-0	TX_MINOR_VER	R	8h	TX Minor Version Value - The value read is the minor version number

**14.5.2.2 TX\_CONTROL Register (offset = 4h) [reset = 0h]**

TX\_CONTROL is shown in [Figure 14-30](#) and described in [Table 14-41](#).

CPDMA\_REGS TX CONTROL REGISTER

**Figure 14-30. TX\_CONTROL Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

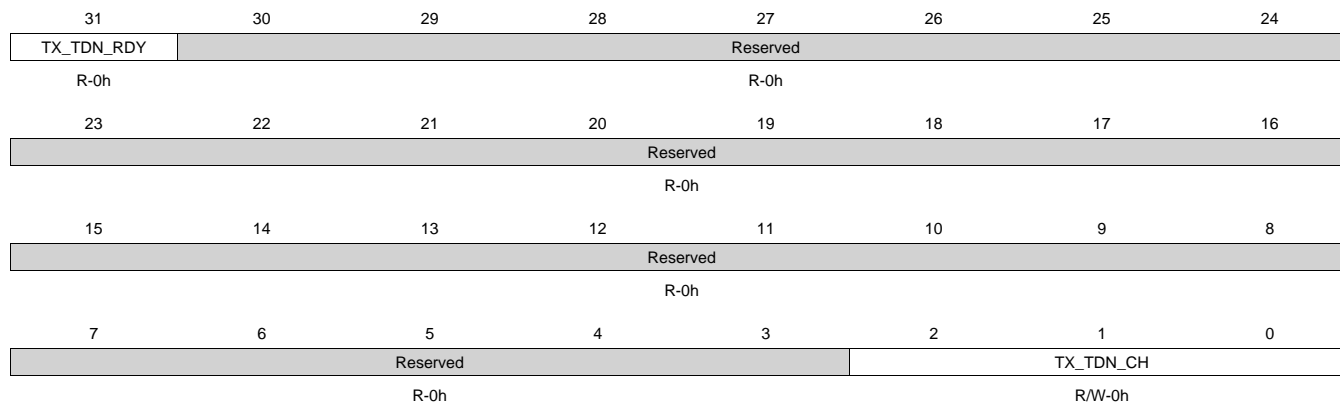

**Table 14-41. TX\_CONTROL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	Reserved	R	0h	
0	TX_EN	R/W	0h	TX Enable 0 - Disabled 1 - Enabled

**14.5.2.3 TX\_TEARDOWN Register (offset = 8h) [reset = 0h]**

 TX\_TEARDOWN is shown in [Figure 14-31](#) and described in [Table 14-42](#).

CPDMA\_REGS TX TEARDOWN REGISTER

**Figure 14-31. TX\_TEARDOWN Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-42. TX\_TEARDOWN Register Field Descriptions**

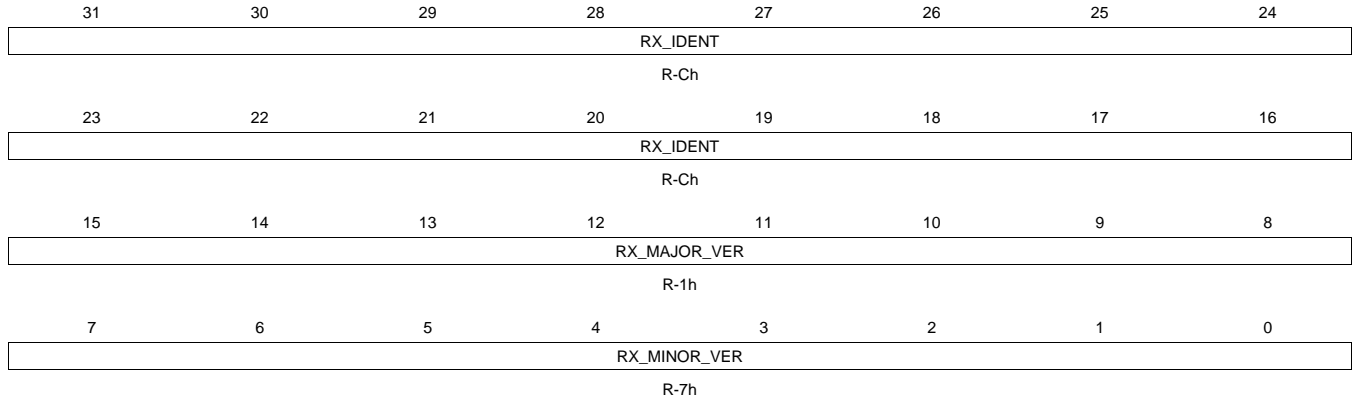

Bit	Field	Type	Reset	Description
31	TX_TDN_RDY	R	0h	Tx Teardown Ready - read as zero, but is always assumed to be one (unused).
30-3	Reserved	R	0h	
2-0	TX_TDN_CH	R/W	0h	Tx Teardown Channel - Transmit channel teardown is commanded by writing the encoded value of the transmit channel to be torn down. The teardown register is read as zero. 000 - teardown transmit channel 0 ... 111 - teardown transmit channel 7

#### 14.5.2.4 RX\_IDVER Register (offset = 10h) [reset = C0107h]

RX\_IDVER is shown in [Figure 14-32](#) and described in [Table 14-43](#).

CPDMA\_REGS RX IDENTIFICATION AND VERSION REGISTER

**Figure 14-32. RX\_IDVER Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

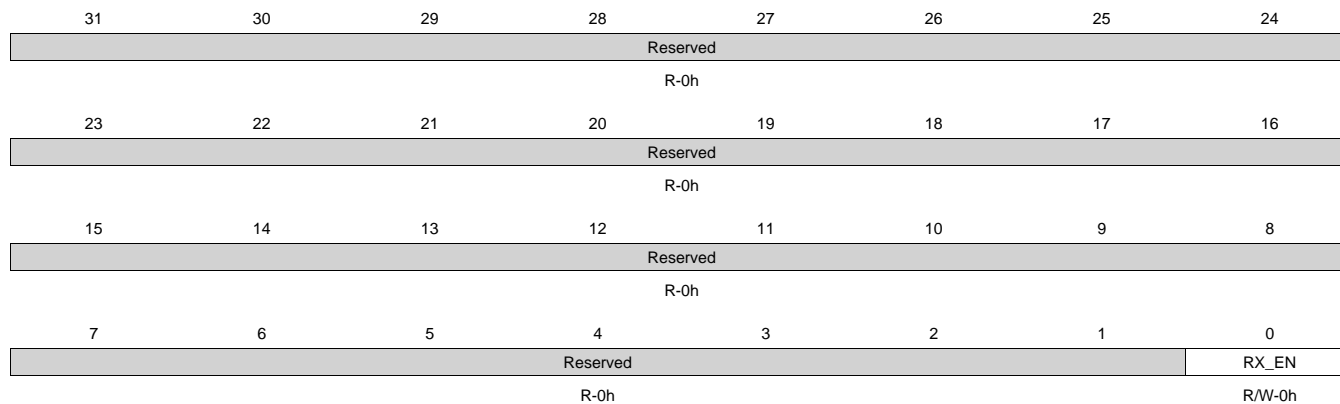

**Table 14-43. RX\_IDVER Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RX_IDENT	R	Ch	RX Identification Value
15-8	RX_MAJOR_VER	R	1h	RX Major Version Value
7-0	RX_MINOR_VER	R	7h	RX Minor Version Value

**14.5.2.5 RX\_CONTROL Register (offset = 14h) [reset = 0h]**

 RX\_CONTROL is shown in [Figure 14-33](#) and described in [Table 14-44](#).

CPDMA\_REGS RX CONTROL REGISTER

**Figure 14-33. RX\_CONTROL Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-44. RX\_CONTROL Register Field Descriptions**

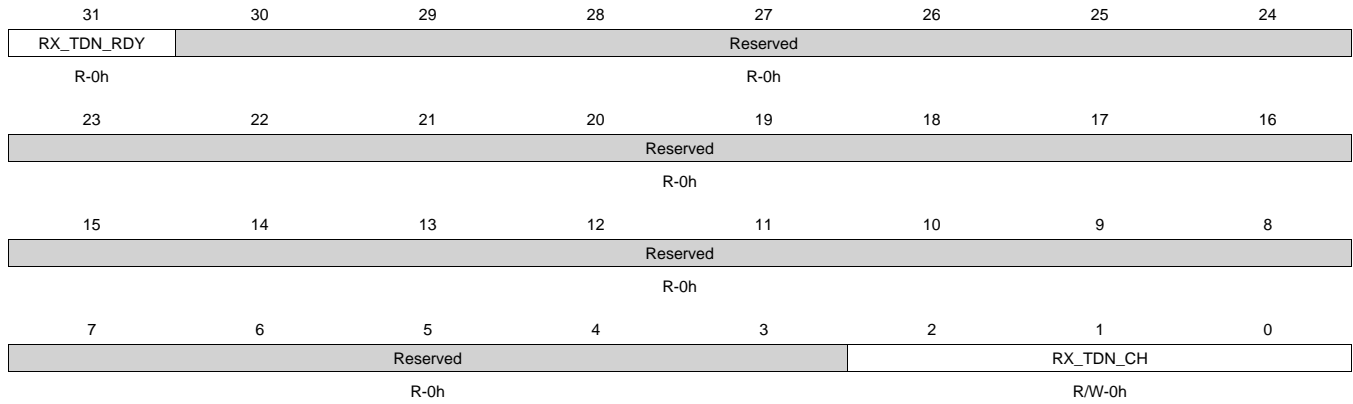

Bit	Field	Type	Reset	Description
31-1	Reserved	R	0h	
0	RX_EN	R/W	0h	RX DMA Enable 0 - Disabled 1 - Enabled

**14.5.2.6 RX\_TEARDOWN Register (offset = 18h) [reset = 0h]**

RX\_TEARDOWN is shown in [Figure 14-34](#) and described in [Table 14-45](#).

CPDMA\_REGS RX TEARDOWN REGISTER

**Figure 14-34. RX\_TEARDOWN Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

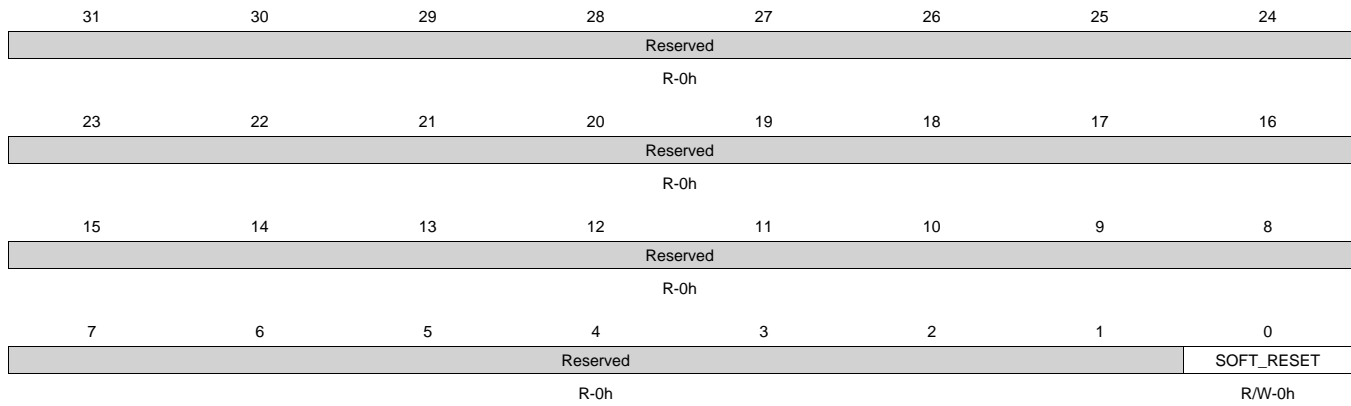

**Table 14-45. RX\_TEARDOWN Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	RX_TDN_RDY	R	0h	Teardown Ready - read as zero, but is always assumed to be one (unused).
30-3	Reserved	R	0h	
2-0	RX_TDN_CH	R/W	0h	Rx Teardown Channel -Receive channel teardown is commanded by writing the encoded value of the receive channel to be torn down. The teardown register is read as zero. 000 - teardown receive channel 0 ... 111 - teardown receive channel 7

**14.5.2.7 CPDMA\_SOFT\_RESET Register (offset = 1Ch) [reset = 0h]**

 CPDMA\_SOFT\_RESET is shown in [Figure 14-35](#) and described in [Table 14-46](#).

CPDMA\_REGS SOFT RESET REGISTER

**Figure 14-35. CPDMA\_SOFT\_RESET Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-46. CPDMA\_SOFT\_RESET Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	Reserved	R	0h	
0	SOFT_RESET	R/W	0h	Software reset - Writing a one to this bit causes the CPDMA logic to be reset. Software reset occurs when the RX and TX DMA Controllers are in an idle state to avoid locking up the VBUSP bus. After writing a one to this bit, it may be polled to determine if the reset has occurred. If a one is read, the reset has not yet occurred. If a zero is read then reset has occurred.

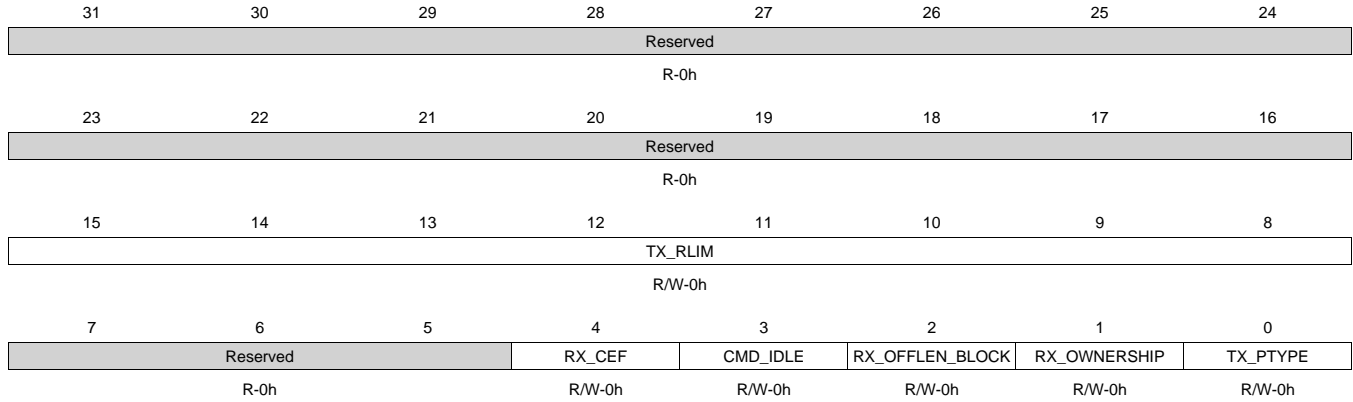

14.5.2.8 DMACONTROL Register (offset = 20h) [reset = 0h]

DMACONTROL is shown in Figure 14-36 and described in Table 14-47.

CPDMA\_REGS CPDMA CONTROL REGISTER

Figure 14-36. DMACONTROL Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

Table 14-47. DMACONTROL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	Reserved	R	0h	
15-8	TX_RLIM	R/W	0h	Transmit Rate Limit Channel Bus 00000000 - no rate-limited channels 10000000 - channel 7 is rate-limited 11000000 - channels 7 downto 6 are rate-limited 11100000 - channels 7 downto 5 are rate-limited 11110000 - channels 7 downto 4 are rate-limited 11111000 - channels 7 downto 3 are rate-limited 11111100 - channels 7 downto 2 are rate-limited 11111110 - channels 7 downto 1 are rate-limited 11111111 - channels 7 downto 0 are rate-limited all others invalid - this bus must be set msb towards lsb. tx_ptype must be set if any tx_rlim bit is set for fixed priority.
7-5	Reserved	R	0h	
4	RX_CEF	R/W	0h	RX Copy Error Frames Enable - Enables DMA overrun frames to be transferred to memory (up to the point of overrun). The overrun error bit will be set in the frame EOP buffer descriptor. Overrun frame data will be filtered when rx_cef is not set. Frames coming from the receive FIFO with other error bits set are not effected by this bit. 0 - Frames containing overrun errors are filtered. 1 - Frames containing overrun errors are transferred to memory.
3	CMD_IDLE	R/W	0h	Command Idle 0 - Idle not commanded 1 - Idle Commanded (read idle in DMAStatus)
2	RX_OFFLEN_BLOCK	R/W	0h	Receive Offset/Length word write block. 0 - Do not block the DMA writes to the receive buffer descriptor offset/buffer length word. The offset/buffer length word is written as specified in CPPI 3.0. 1 - Block all CPDMA DMA controller writes to the receive buffer descriptor offset/buffer length words during CPPI packet processing. when this bit is set, the CPDMA will never write the third word to any receive buffer descriptor.

**Table 14-47. DMACONTROL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1	RX_OWNERSHIP	R/W	0h	<p>Receive Ownership Write Bit Value.</p> <p>0 - The CPDMA writes the receive ownership bit to zero at the end of packet processing as specified in CPPI 3.0.</p> <p>1 - The CPDMA writes the receive ownership bit to one at the end of packet processing.</p> <p>Users who do not use the ownership mechanism can use this mode to preclude the necessity of software having to set this bit each time the buffer descriptor is used.</p>
0	TX_PTYPE	R/W	0h	<p>Transmit Queue Priority Type</p> <p>0 - The queue uses a round robin scheme to select the next channel for transmission.</p> <p>1 - The queue uses a fixed (channel 7 highest priority) priority scheme to select the next channel for transmission</p>

### 14.5.2.9 DMASTATUS Register (offset = 24h) [reset = 0h]

DMASTATUS is shown in [Figure 14-37](#) and described in [Table 14-48](#).

CPDMA\_REGS CPDMA STATUS REGISTER

**Figure 14-37. DMASTATUS Register**

31	30	29	28	27	26	25	24
IDLE	Reserved						
R-0h				R-0h			
23	22	21	20	19	18	17	16

RX_HOST_ERR_CODE				Reserved	RX_ERR_CH		
R-0h				R-0h	R-0h		
7	6	5	4	3	2	1	0
Reserved							
R-0h							

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-48. DMASTATUS Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	IDLE	R	0h	Idle Status Bit - Indicates when set that the CPDMA is not transferring a packet on transmit or receive.
30-24	Reserved	R	0h	
23-20	TX_HOST_ERR_CODE	R	0h	TX Host Error Code - This field is set to indicate CPDMA detected TX DMA related host errors. The host should read this field after a HOST_ERR_INT to determine the error. Host error Interrupts require hardware reset in order to recover. A zero packet length is an error, but it is not detected. 0000 - No error 0001 - SOP error. 0010 - Ownership bit not set in SOP buffer. 0011 - Zero Next Buffer Descriptor Pointer Without EOP 0100 - Zero Buffer Pointer. 0101 - Zero Buffer Length 0110 - Packet Length Error (sum of buffers is less than packet length) 0111 - reserved ... 1111 - reserved
19	Reserved	R	0h	
18-16	TX_ERR_CH	R	0h	TX Host Error Channel - This field indicates which TX channel (if applicable) the host error occurred on. This field is cleared to zero on a host read. 000 - The host error occurred on TX channel 0 ... 111 - The host error occurred on TX channel 7
15-12	RX_HOST_ERR_CODE	R	0h	RX Host Error Code - This field is set to indicate CPDMA detected RX DMA related host errors. The host should read this field after a HOST_ERR_INT to determine the error. Host error Interrupts require hardware reset in order to recover. 0000 - No error 0001 - reserved 0010 - Ownership bit not set in input buffer. 0011 - reserved 0100 - Zero Buffer Pointer. 0101 - Zero buffer length on non-SOP descriptor 0110 - SOP buffer length not greater than offset ... 1111 - reserved

**Table 14-48. DMASTATUS Register Field Descriptions (continued)**

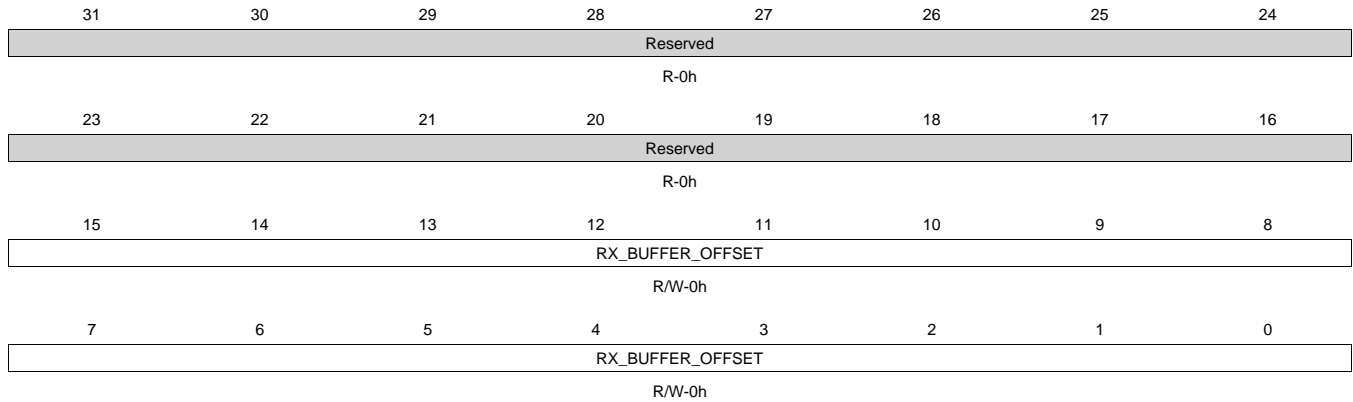

Bit	Field	Type	Reset	Description
11	Reserved	R	0h	
10-8	RX_ERR_CH	R	0h	RX Host Error Channel - This field indicates which RX channel the host error occurred on. This field is cleared to zero on a host read. 000 - The host error occurred on RX channel 0 ... 111 - The host error occurred on RX channel 7
7-0	Reserved	R	0h	

**14.5.2.10 RX\_BUFFER\_OFFSET Register (offset = 28h) [reset = 0h]**

RX\_BUFFER\_OFFSET is shown in [Figure 14-38](#) and described in [Table 14-49](#).

CPDMA\_REGS RECEIVE BUFFER OFFSET

**Figure 14-38. RX\_BUFFER\_OFFSET Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

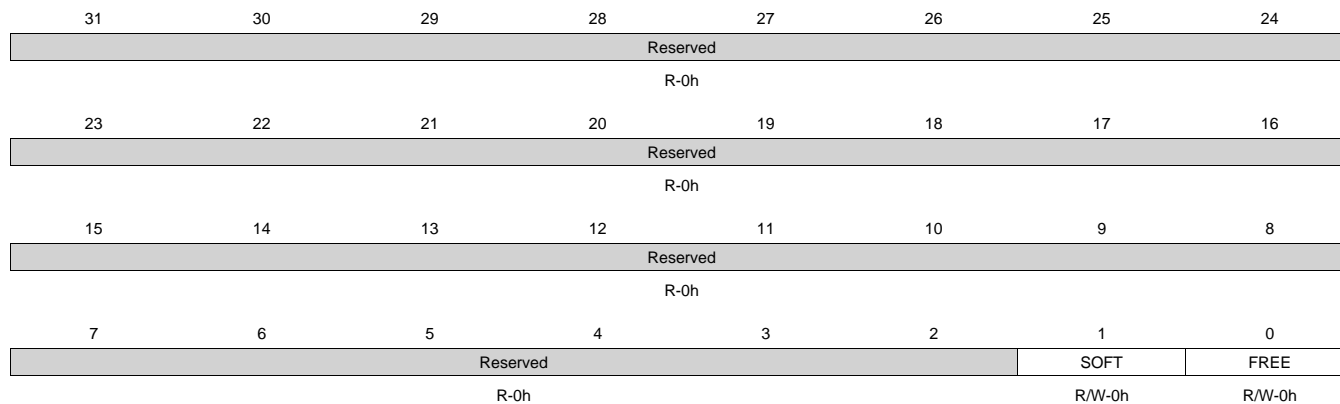

**Table 14-49. RX\_BUFFER\_OFFSET Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	Reserved	R	0h	
15-0	RX_BUFFER_OFFSET	R/W	0h	Receive Buffer Offset Value - The rx_buffer_offset will be written by the port into each frame SOP buffer descriptor buffer_offset field. The frame data will begin after the rx_buffer_offset value of bytes. A value of 0x0000 indicates that there are no unused bytes at the beginning of the data and that valid data begins on the first byte of the buffer. A value of 0x000F (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. This value is used for all channels.

**14.5.2.11 EMCONTROL Register (offset = 2Ch) [reset = 0h]**

 EMCONTROL is shown in [Figure 14-39](#) and described in [Table 14-50](#).

CPDMA\_REGS EMULATION CONTROL

**Figure 14-39. EMCONTROL Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

CPTS\_CONTROL is shown in Figure 14-79 and described in Table 14-91.

#### TIME SYNC CONTROL REGISTER

**Figure 14-79. CPTS\_CONTROL Register**

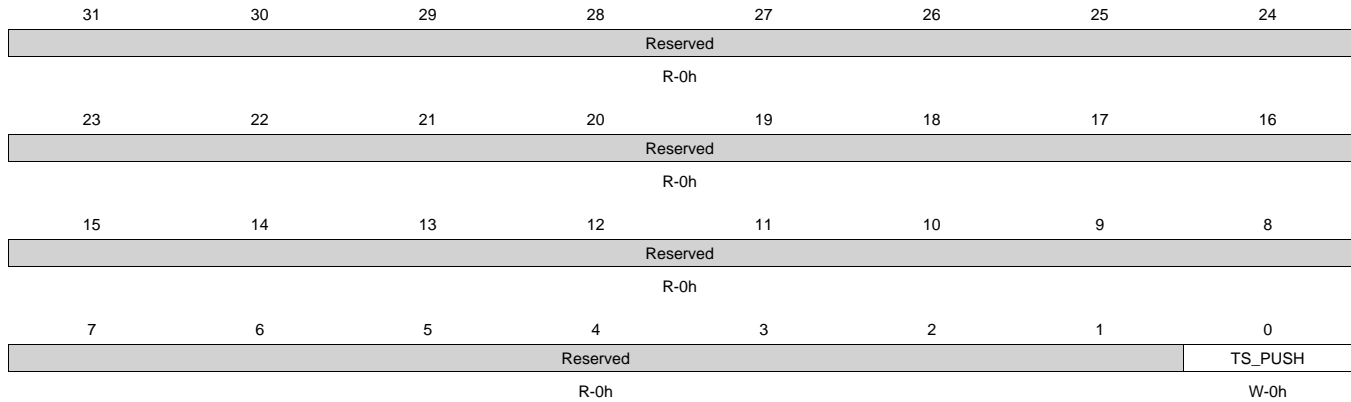

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-91. CPTS\_CONTROL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-12	Reserved	R	0h	
11	HW4_TS_PUSH_EN	R/W	0h	Hardware push 4 enable
10	HW3_TS_PUSH_EN	R/W	0h	Hardware push 3 enable
9	HW2_TS_PUSH_EN	R/W	0h	Hardware push 2 enable
8	HW1_TS_PUSH_EN	R/W	0h	Hardware push 1 enable
7-2	Reserved	R	0h	
1	INT_TEST	R/W	0h	Interrupt Test - When set, this bit allows the raw interrupt to be written to facilitate interrupt test.
0	CPTS_EN	R/W	0h	Time Sync Enable - When disabled (cleared to zero), the RCLK domain is held in reset. 0 - Time Sync Disabled 1 - Time Sync Enabled

**14.5.3.3 CPTS\_TS\_PUSH Register (offset = Ch) [reset = 0h]**

 CPTS\_TS\_PUSH is shown in [Figure 14-80](#) and described in [Table 14-92](#).

**TIME STAMP EVENT PUSH REGISTER**
**Figure 14-80. CPTS\_TS\_PUSH Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-92. CPTS\_TS\_PUSH Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	Reserved	R	0h	
0	TS_PUSH	W	0h	Time stamp event push - When a logic high is written to this bit a time stamp event is pushed onto the event FIFO. The time stamp value is the time of the write of this register, not the time of the event read. The time stamp value can then be read on interrupt via the event registers. Software should not push a second time stamp event onto the event FIFO until the first time stamp value has been read from the event FIFO (there should be only one time stamp event in the event FIFO at any given time). This bit is write only and always reads zero.

#### 14.5.3.4 CPTS\_TS\_LOAD\_VAL Register (offset = 10h) [reset = 0h]

CPTS\_TS\_LOAD\_VAL is shown in [Figure 14-81](#) and described in [Table 14-93](#).

#### TIME STAMP LOAD VALUE REGISTER

**Figure 14-81. CPTS\_TS\_LOAD\_VAL Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

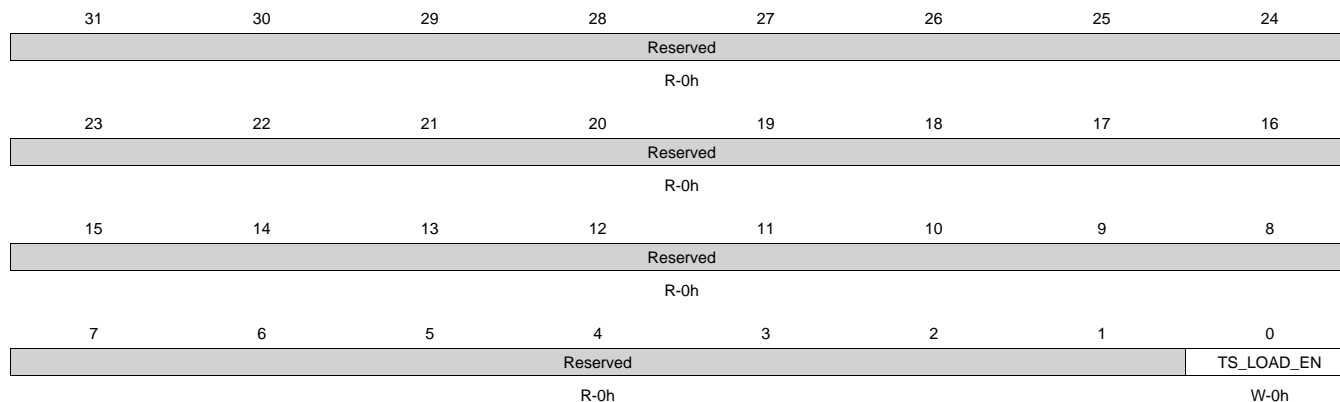

**Table 14-93. CPTS\_TS\_LOAD\_VAL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TS_LOAD_VAL	R/W	0h	Time Stamp Load Value - Writing the ts_load_en bit causes the value contained in this register to be written into the time stamp. The time stamp value is read by initiating a time stamp push event, not by reading this register. When reading this register, the value read is not the time stamp, but is the value that was last written to this register.

**14.5.3.5 CPTS\_TS\_LOAD\_EN Register (offset = 14h) [reset = 0h]**

 CPTS\_TS\_LOAD\_EN is shown in [Figure 14-82](#) and described in [Table 14-94](#).

TIME STAMP LOAD ENABLE REGISTER

**Figure 14-82. CPTS\_TS\_LOAD\_EN Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-94. CPTS\_TS\_LOAD\_EN Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	Reserved	R	0h	
0	TS_LOAD_EN	W	0h	Time Stamp Load - Writing a one to this bit enables the time stamp value to be written via the ts_load_val[31:0] register. This feature is included for test purposes. This bit is write only.

**14.5.3.6 CPTS\_INTSTAT\_RAW Register (offset = 20h) [reset = 0h]**

CPTS\_INTSTAT\_RAW is shown in [Figure 14-83](#) and described in [Table 14-95](#).

TIME SYNC INTERRUPT STATUS RAW REGISTER

**Figure 14-83. CPTS\_INTSTAT\_RAW Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

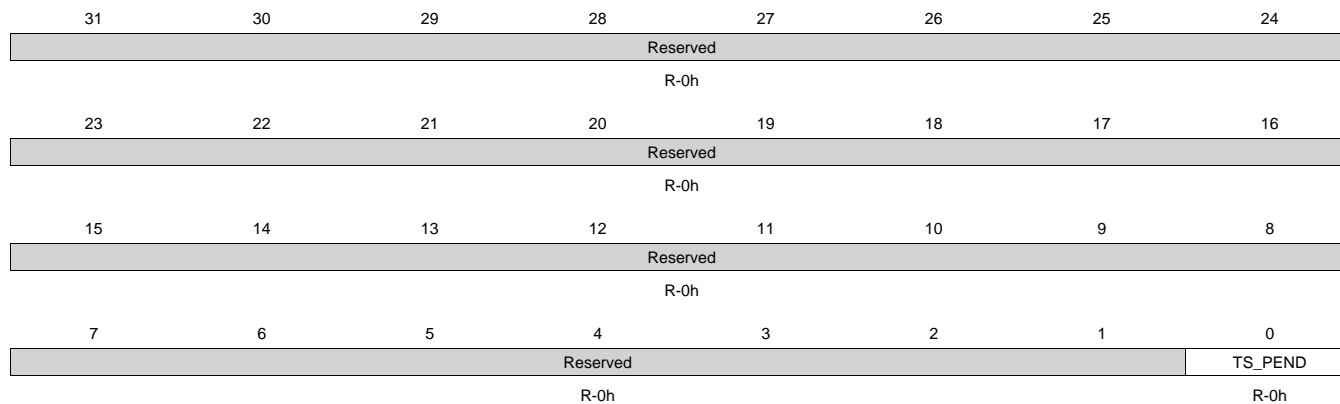

**Table 14-95. CPTS\_INTSTAT\_RAW Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	Reserved	R	0h	
0	TS_PEND_RAW	R/W	0h	TS_PEND_RAW int read (before enable). Writable when int_test = 1 A one in this bit indicates that there is one or more events in the event FIFO.

**14.5.3.7 CPTS\_INTSTAT\_MASKED Register (offset = 24h) [reset = 0h]**

 CPTS\_INTSTAT\_MASKED is shown in [Figure 14-84](#) and described in [Table 14-96](#).

TIME SYNC INTERRUPT STATUS MASKED REGISTER

**Figure 14-84. CPTS\_INTSTAT\_MASKED Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-96. CPTS\_INTSTAT\_MASKED Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	Reserved	R	0h	
0	TS_PEND	R	0h	TS_PEND masked interrupt read (after enable).

**14.5.3.8 CPTS\_INT\_ENABLE Register (offset = 28h) [reset = 0h]**

CPTS\_INT\_ENABLE is shown in [Figure 14-85](#) and described in [Table 14-97](#).

TIME SYNC INTERRUPT ENABLE REGISTER

**Figure 14-85. CPTS\_INT\_ENABLE Register**

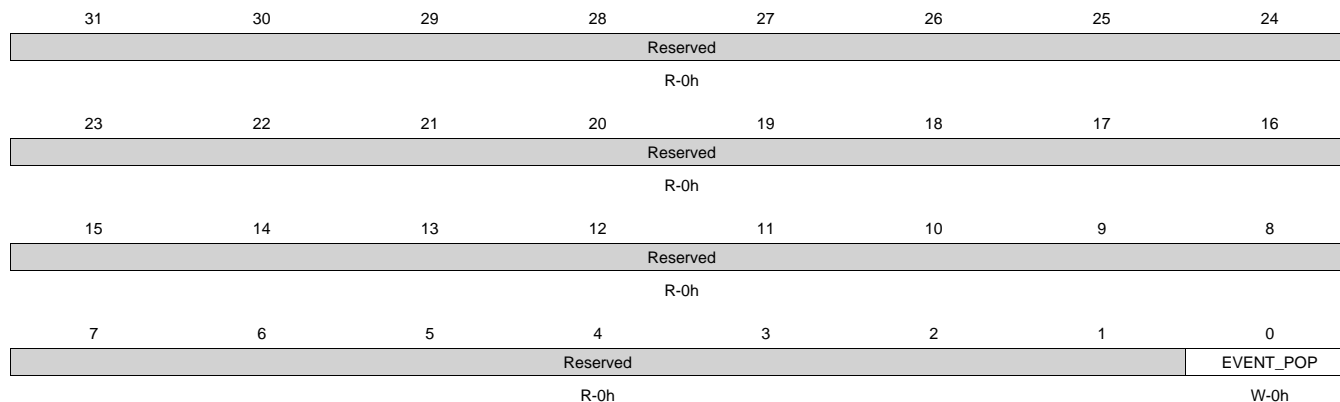

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-97. CPTS\_INT\_ENABLE Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	Reserved	R	0h	
0	TS_PEND_EN	R/W	0h	TS_PEND masked interrupt enable.

**14.5.3.9 CPTS\_EVENT\_POP Register (offset = 30h) [reset = 0h]**

 CPTS\_EVENT\_POP is shown in [Figure 14-86](#) and described in [Table 14-98](#).

**EVENT INTERRUPT POP REGISTER**
**Figure 14-86. CPTS\_EVENT\_POP Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-98. CPTS\_EVENT\_POP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	Reserved	R	0h	
0	EVENT_POP	W	0h	Event Pop - When a logic high is written to this bit an event is popped off the event FIFO. The event FIFO pop occurs as part of the interrupt process after the event has been read in the Event_Low and Event_High registers. Popping an event discards the event and causes the next event, if any, to be moved to the top of the FIFO ready to be read by software on interrupt.

**14.5.3.10 CPTS\_EVENT\_LOW Register (offset = 34h) [reset = 0h]**

CPTS\_EVENT\_LOW is shown in [Figure 14-87](#) and described in [Table 14-99](#).

LOWER 32-BITS OF THE EVENT VALUE

**Figure 14-87. CPTS\_EVENT\_LOW Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-99. CPTS\_EVENT\_LOW Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TIME_STAMP	R	0h	Time Stamp - The timestamp is valid for transmit, receive, and time stamp push event types. The timestamp value is not valid for counter roll event types.

**14.5.3.11 CPTS\_EVENT\_HIGH Register (offset = 38h) [reset = 0h]**

 CPTS\_EVENT\_HIGH is shown in [Figure 14-88](#) and described in [Table 14-100](#).

UPPER 32-BITS OF THE EVENT VALUE

**Figure 14-88. CPTS\_EVENT\_HIGH Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-100. CPTS\_EVENT\_HIGH Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-29	Reserved	R	0h	
28-24	PORT_NUMBER	R	0h	Port Number - indicates the port number of an ethernet event or the hardware push pin number (1 to 4).
23-20	EVENT_TYPE	R	0h	Time Sync Event Type 0000 - Time Stamp Push Event 0001 - Time Stamp Rollover Event 0010 - Time Stamp Half Rollover Event 0011 - Hardware Time Stamp Push Event 0100 - Ethernet Receive Event 0101 - Ethernet Transmit Event
19-16	MESSAGE_TYPE	R	0h	Message type - The message type value that was contained in an ethernet transmit or receive time sync packet. This field is valid only for ethernet transmit or receive events.
15-0	SEQUENCE_ID	R	0h	Sequence ID - The 16-bit sequence id is the value that was contained in an ethernet transmit or receive time sync packet. This field is valid only for ethernet transmit or receive events.

### 14.5.4 CPSW\_STATS Registers

For a full description of the CPSW\_STATS registers, see [Section 14.3.2.20, CPSW\\_3G Network Statistics](#). The registers are summarized in [Table 14-101](#).

**Table 14-101. CPSW\_STATS REGISTERS**

Offset	Acronym	Register Name	Section
00h		Good Rx Frames	<a href="#">Section 14.3.2.20.1.1</a>
04h		Broadcast Rx Frames	<a href="#">Section 14.3.2.20.1.2</a>
08h		Multicast Rx Frames	<a href="#">Section 14.3.2.20.1.3</a>
0Ch		Pause Rx Frames	<a href="#">Section 14.3.2.20.1.4</a>
10h		Rx CRC Errors	<a href="#">Section 14.3.2.20.1.5</a>
14h		Rx Align/Code Errors	<a href="#">Section 14.3.2.20.1.6</a>
18h		Oversize Rx Frames	<a href="#">Section 14.3.2.20.1.7</a>
1Ch		Rx Jabbers	<a href="#">Section 14.3.2.20.1.8</a>
20h		Undersize (Short) Rx Frames	<a href="#">Section 14.3.2.20.1.9</a>
24h		Rx Fragments	<a href="#">Section 14.3.2.20.1.10</a>
30h		Rx Octets	<a href="#">Section 14.3.2.20.1.14</a>
34h		Good Tx Frames	<a href="#">Section 14.3.2.20.2.1</a>
38h		Broadcast Tx Frames	<a href="#">Section 14.3.2.20.2.2</a>
3Ch		Multicast Tx Frames	<a href="#">Section 14.3.2.20.2.3</a>
40h		Pause Tx Frames	<a href="#">Section 14.3.2.20.2.4</a>
44h		Deferred Tx Frames	<a href="#">Section 14.3.2.20.2.11</a>
48h		Collisions	<a href="#">Section 14.3.2.20.2.5</a>
4Ch		Single Collision Tx Frames	<a href="#">Section 14.3.2.20.2.6</a>
50h		Multiple Collision Tx Frames	<a href="#">Section 14.3.2.20.2.7</a>
54h		Excessive Collisions	<a href="#">Section 14.3.2.20.2.8</a>
58h		Late Collisions	<a href="#">Section 14.3.2.20.2.9</a>
5Ch		Tx Underrun	<a href="#">Section 14.3.2.20.2.10</a>
60h		Carrier Sense Errors	<a href="#">Section 14.3.2.20.2.12</a>
64h		Tx Octets	<a href="#">Section 14.3.2.20.2.13</a>
68h		Rx + Tx 64 Octet Frames	<a href="#">Section 14.3.2.20.3.1</a>
6Ch		Rx + Tx 65–127 Octet Frames	<a href="#">Section 14.3.2.20.3.2</a>
70h		Rx + Tx 128–255 Octet Frames	<a href="#">Section 14.3.2.20.3.3</a>
74h		Rx + Tx 256–511 Octet Frames	<a href="#">Section 14.3.2.20.3.4</a>
78h		Rx + Tx 512–1023 Octet Frames	<a href="#">Section 14.3.2.20.3.5</a>
7Ch		Rx + Tx 1024_Up Octet Frames	<a href="#">Section 14.3.2.20.3.6</a>
80h		Net Octets	<a href="#">Section 14.3.2.20.1.15</a>
84h		Rx Start of Frame Overruns	<a href="#">Section 14.3.2.20.1.11</a>
88h		Rx Middle of Frame Overruns	<a href="#">Section 14.3.2.20.1.12</a>
8Ch		Rx DMA Overruns	<a href="#">Section 14.3.2.20.1.13</a>

### 14.5.5 CPDMA\_STATERAM Registers

[Table 14-102](#) lists the memory-mapped registers for the CPSW\_CPDMA. All register offset addresses not listed in [Table 14-102](#) should be considered as reserved locations and the register contents should not be modified.

**Table 14-102. CPDMA\_STATERAM REGISTERS**

Offset	Acronym	Register Name	Section
00h	TX0_HDP	CPDMA_STATERAM TX CHANNEL 0 HEAD DESC POINTER *	<a href="#">Section 14.5.5.1</a>

**Table 14-102. CPDMA\_STATERAM REGISTERS (continued)**

Offset	Acronym	Register Name	Section
04h	TX1_HDP	CPDMA_STATERAM TX CHANNEL 1 HEAD DESC POINTER *	<a href="#">Section 14.5.5.2</a>
08h	TX2_HDP	CPDMA_STATERAM TX CHANNEL 2 HEAD DESC POINTER *	<a href="#">Section 14.5.5.3</a>

### 14.5.5.1 TX0\_HDP Register (offset = A00h) [reset = 0h]

TX0\_HDP is shown in [Figure 14-89](#) and described in [Table 14-103](#).

CPDMA\_STATERAM TX CHANNEL 0 HEAD DESC POINTER \*

**Figure 14-89. TX0\_HDP Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-103. TX0\_HDP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TX_HDP	R/W	0h	TX Channel (0..7) DMA Head Descriptor Pointer - Writing a TX DMA Buffer Descriptor address to a head pointer location initiates TX DMA operations in the queue for the selected channel. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.

**14.5.5.2 TX1\_HDP Register (offset = A04h) [reset = 0h]**

TX1\_HDP is shown in [Figure 14-90](#) and described in [Table 14-104](#).

CPDMA\_STATERAM TX CHANNEL 1 HEAD DESC POINTER \*

**Figure 14-90. TX1\_HDP Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-104. TX1\_HDP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TX_HDP	R/W	0h	TX Channel (0..7) DMA Head Descriptor Pointer - Writing a TX DMA Buffer Descriptor address to a head pointer location initiates TX DMA operations in the queue for the selected channel. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.

### 14.5.5.3 TX2\_HDP Register (offset = A08h) [reset = 0h]

TX2\_HDP is shown in [Figure 14-91](#) and described in [Table 14-105](#).

CPDMA\_STATERAM TX CHANNEL 2 HEAD DESC POINTER \*

**Figure 14-91. TX2\_HDP Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-105. TX2\_HDP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TX_HDP	R/W	0h	TX Channel (0..7) DMA Head Descriptor Pointer - Writing a TX DMA Buffer Descriptor address to a head pointer location initiates TX DMA operations in the queue for the selected channel. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.

**14.5.5.4 TX3\_HDP Register (offset = A0Ch) [reset = 0h]**

TX3\_HDP is shown in [Figure 14-92](#) and described in [Table 14-106](#).

CPDMA\_STATERAM TX CHANNEL 3 HEAD DESC POINTER \*

**Figure 14-92. TX3\_HDP Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-106. TX3\_HDP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TX_HDP	R/W	0h	TX Channel (0..7) DMA Head Descriptor Pointer - Writing a TX DMA Buffer Descriptor address to a head pointer location initiates TX DMA operations in the queue for the selected channel. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.

### 14.5.5.5 TX4\_HDP Register (offset = A10h) [reset = 0h]

TX4\_HDP is shown in [Figure 14-93](#) and described in [Table 14-107](#).

CPDMA\_STATERAM TX CHANNEL 4 HEAD DESC POINTER \*

**Figure 14-93. TX4\_HDP Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-107. TX4\_HDP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TX_HDP	R/W	0h	TX Channel (0..7) DMA Head Descriptor Pointer - Writing a TX DMA Buffer Descriptor address to a head pointer location initiates TX DMA operations in the queue for the selected channel. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.

**14.5.5.6 TX5\_HDP Register (offset = A14h) [reset = 0h]**

TX5\_HDP is shown in [Figure 14-94](#) and described in [Table 14-108](#).

CPDMA\_STATERAM TX CHANNEL 5 HEAD DESC POINTER \*

**Figure 14-94. TX5\_HDP Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-108. TX5\_HDP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TX_HDP	R/W	0h	TX Channel (0..7) DMA Head Descriptor Pointer - Writing a TX DMA Buffer Descriptor address to a head pointer location initiates TX DMA operations in the queue for the selected channel. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.

### 14.5.5.7 TX6\_HDP Register (offset = A18h) [reset = 0h]

TX6\_HDP is shown in [Figure 14-95](#) and described in [Table 14-109](#).

CPDMA\_STATERAM TX CHANNEL 6 HEAD DESC POINTER \*

**Figure 14-95. TX6\_HDP Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-109. TX6\_HDP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TX_HDP	R/W	0h	TX Channel (0..7) DMA Head Descriptor Pointer - Writing a TX DMA Buffer Descriptor address to a head pointer location initiates TX DMA operations in the queue for the selected channel. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.

**14.5.5.8 TX7\_HDP Register (offset = A1Ch) [reset = 0h]**

TX7\_HDP is shown in [Figure 14-96](#) and described in [Table 14-110](#).

CPDMA\_STATERAM TX CHANNEL 7 HEAD DESC POINTER \*

**Figure 14-96. TX7\_HDP Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-110. TX7\_HDP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TX_HDP	R/W	0h	TX Channel (0..7) DMA Head Descriptor Pointer - Writing a TX DMA Buffer Descriptor address to a head pointer location initiates TX DMA operations in the queue for the selected channel. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.

### 14.5.5.9 RX0\_HDP Register (offset = A20h) [reset = 0h]

RX0\_HDP is shown in [Figure 14-97](#) and described in [Table 14-111](#).

CPDMA\_STATERAM RX 0 CHANNEL 0 HEAD DESC POINTER \*

**Figure 14-97. RX0\_HDP Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-111. RX0\_HDP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	RX_HDP	R/W	0h	RX DMA Head Descriptor Pointer - Writing an RX DMA Buffer Descriptor address to this location allows RX DMA operations in the selected channel when a channel frame is received. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.

**14.5.5.10 RX1\_HDP Register (offset = A24h) [reset = 0h]**

RX1\_HDP is shown in [Figure 14-98](#) and described in [Table 14-112](#).

CPDMA\_STATERAM RX 1 CHANNEL 1 HEAD DESC POINTER \*

**Figure 14-98. RX1\_HDP Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-112. RX1\_HDP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	RX_HDP	R/W	0h	RX DMA Head Descriptor Pointer - Writing an RX DMA Buffer Descriptor address to this location allows RX DMA operations in the selected channel when a channel frame is received. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.

**14.5.5.11 RX2\_HDP Register (offset = A28h) [reset = 0h]**

RX2\_HDP is shown in [Figure 14-99](#) and described in [Table 14-113](#).

CPDMA\_STATERAM RX 2 CHANNEL 2 HEAD DESC POINTER \*

**Figure 14-99. RX2\_HDP Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-113. RX2\_HDP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	RX_HDP	R/W	0h	RX DMA Head Descriptor Pointer - Writing an RX DMA Buffer Descriptor address to this location allows RX DMA operations in the selected channel when a channel frame is received. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.

**14.5.5.12 RX3\_HDP Register (offset = A2Ch) [reset = 0h]**

RX3\_HDP is shown in [Figure 14-100](#) and described in [Table 14-114](#).

CPDMA\_STATERAM RX 3 CHANNEL 3 HEAD DESC POINTER \*

**Figure 14-100. RX3\_HDP Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-114. RX3\_HDP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	RX_HDP	R/W	0h	RX DMA Head Descriptor Pointer - Writing an RX DMA Buffer Descriptor address to this location allows RX DMA operations in the selected channel when a channel frame is received. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.

**14.5.5.13 RX4\_HDP Register (offset = A30h) [reset = 0h]**

RX4\_HDP is shown in [Figure 14-101](#) and described in [Table 14-115](#).

CPDMA\_STATERAM RX 4 CHANNEL 4 HEAD DESC POINTER \*

Reserved							

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

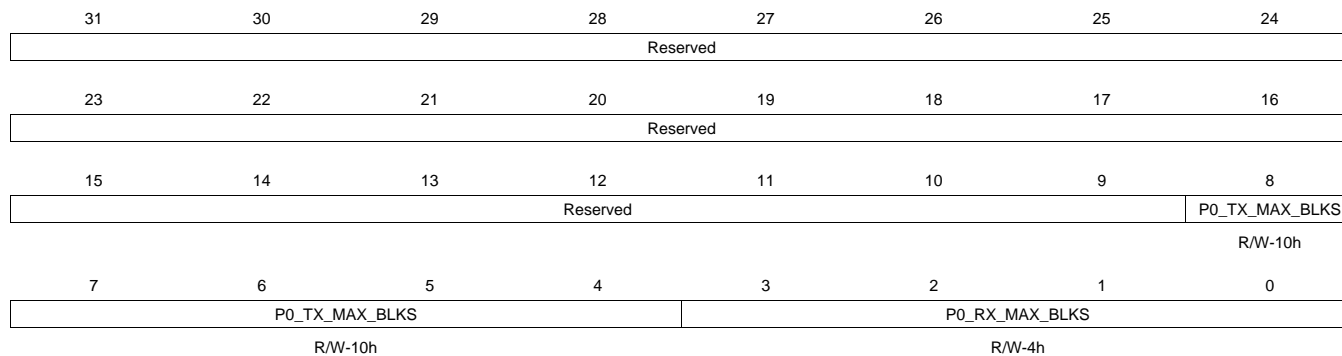

**Table 14-136. P0\_CONTROL Register Field Descriptions**

Bit	Field	Type	Reset	Description
30-28	P0_DLR_CPDMA_CH	R/W	0h	Port 0 DLR CPDMA Channel This field indicates the CPDMA channel that DLR packets will be received on.
24	P0_PASS_PRI_TAGGED	R/W	0h	Port 0 Pass Priority Tagged 0 - Priority tagged packets have the zero VID replaced with the input port P0_PORT_VLAN [11:0] 1 - Priority tagged packets are processed unchanged.
21	P0_VLAN_LTYPE2_EN	R/W	0h	Port 0 VLAN LTYPE 2 enable 0 - disabled 1 - enabled
20	P0_VLAN_LTYPE1_EN	R/W	0h	Port 0 VLAN LTYPE 1 enable 0 - disabled 1 - enabled
16	P0_DSCP_PRI_EN	R/W	0h	Port 0 DSCP Priority Enable 0 - DSCP priority disabled 1 - DSCP priority enabled. All non-tagged IPV4 packets have their received packet priority determined by mapping the 6 TOS bits through the port DSCP priority mapping registers.

**14.5.6.2 P0\_MAX\_BLKs Register (offset = 8h) [reset = 104h]**

 P0\_MAX\_BLKs is shown in [Figure 14-122](#) and described in [Table 14-137](#).

CPSW PORT 0 MAXIMUM FIFO BLOCKS REGISTER

**Figure 14-122. P0\_MAX\_BLKs Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

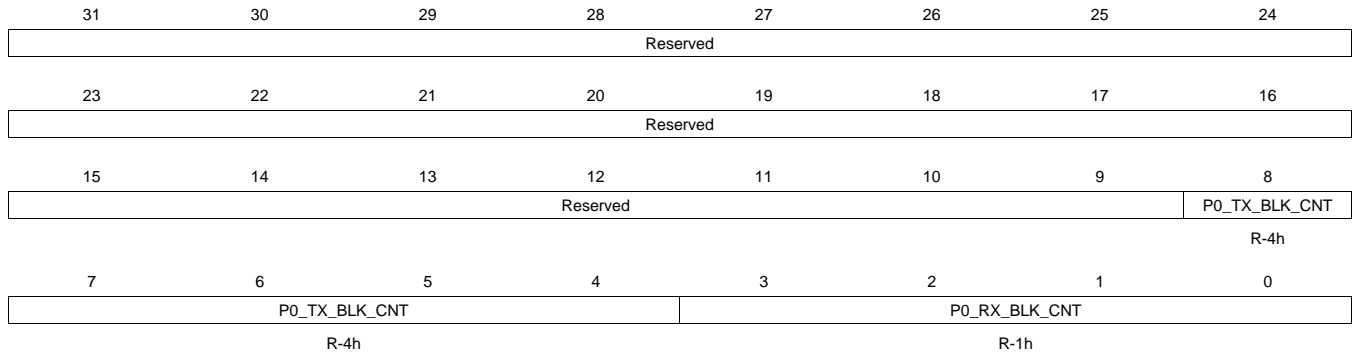

**Table 14-137. P0\_MAX\_BLKs Register Field Descriptions**

Bit	Field	Type	Reset	Description
8-4	P0_TX_MAX_BLKs	R/W	10h	Transmit FIFO Maximum Blocks - This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical transmit priority queues. 0x10 is the recommended value of p0_tx_max_blks. Port 0 should remain in flow control mode. 0xe is the minimum value tx max blks.
3-0	P0_RX_MAX_BLKs	R/W	4h	Receive FIFO Maximum Blocks - This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical receive queue. 0x4 is the recommended value. 0x3 is the minimum value rx max blks and 0x6 is the maximum value.

**14.5.6.3 P0\_BLK\_CNT Register (offset = Ch) [reset = 41h]**

P0\_BLK\_CNT is shown in [Figure 14-123](#) and described in [Table 14-138](#).

CPSW PORT 0 FIFO BLOCK USAGE COUNT (READ ONLY)

**Figure 14-123. P0\_BLK\_CNT Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

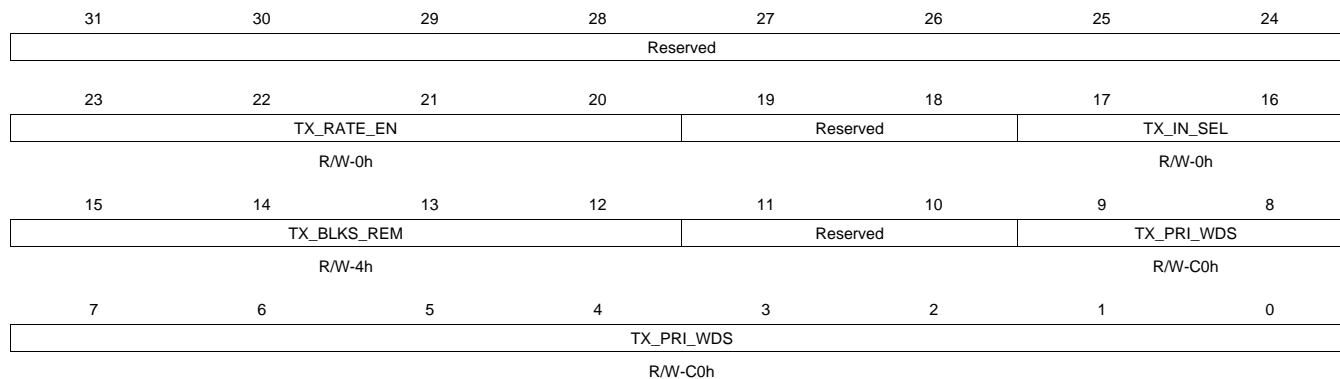

**Table 14-138. P0\_BLK\_CNT Register Field Descriptions**

Bit	Field	Type	Reset	Description
8-4	P0_TX_BLK_CNT	R	4h	Port 0 Transmit Block Count Usage - This value is the number of blocks allocated to the FIFO logical transmit queues.
3-0	P0_RX_BLK_CNT	R	1h	Port 0 Receive Block Count Usage - This value is the number of blocks allocated to the FIFO logical receive queues.

**14.5.6.4 P0\_TX\_IN\_CTL Register (offset = 10h) [reset = 40C0h]**

 P0\_TX\_IN\_CTL is shown in [Figure 14-124](#) and described in [Table 14-139](#).

CPSW PORT 0 TRANSMIT FIFO CONTROL

**Figure 14-124. P0\_TX\_IN\_CTL Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-139. P0\_TX\_IN\_CTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
23-20	TX_RATE_EN	R/W	0h	Transmit FIFO Input Rate Enable
17-16	TX_IN_SEL	R/W	0h	Transmit FIFO Input Queue Type Select 00 - Normal priority mode 01 - Dual MAC mode 10 - Rate Limit mode 11 - reserved Note that Dual MAC mode is not compatible with escalation or shaping because dual mac mode forces round robin priority on FIFO egress.
15-12	TX_BLKs_REM	R/W	4h	Transmit FIFO Input Blocks to subtract in dual mac mode
9-0	TX_PRI_WDS	R/W	C0h	Transmit FIFO Words in queue

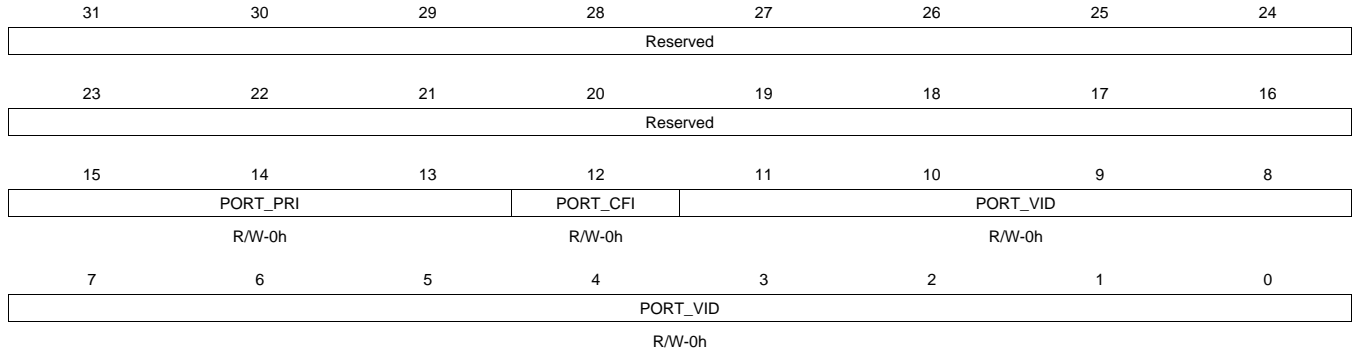

**14.5.6.5 P0\_PORT\_VLAN Register (offset = 14h) [reset = 0h]**

P0\_PORT\_VLAN is shown in [Figure 14-125](#) and described in [Table 14-140](#).

CPSW PORT 0 VLAN REGISTER

**Figure 14-125. P0\_PORT\_VLAN Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-140. P0\_PORT\_VLAN Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-13	PORT_PRI	R/W	0h	Port VLAN Priority (7 is highest priority)
12	PORT_CFI	R/W	0h	Port CFI bit
11-0	PORT_VID	R/W	0h	Port VLAN ID

**14.5.6.6 P0\_TX\_PRI\_MAP Register (offset = 18h) [reset = 33221001h]**

 P0\_TX\_PRI\_MAP is shown in [Figure 14-126](#) and described in [Table 14-141](#).

CPSW PORT 0 TX HEADER PRI TO SWITCH PRI MAPPING REGISTER

0	P1_TS_RX_EN	R/W	0h	Port 1 Time Sync Receive Enable 0 - Port 1 Receive Time Sync disabled 1 - Port 1 Receive Time Sync enabled

**14.5.6.18 P1\_MAX\_BLKs Register (offset = 108h) [reset = 113h]**

P1\_MAX\_BLKs is shown in [Figure 14-138](#) and described in [Table 14-153](#).

CPSW PORT 1 MAXIMUM FIFO BLOCKS REGISTER

**Figure 14-138. P1\_MAX\_BLKs Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

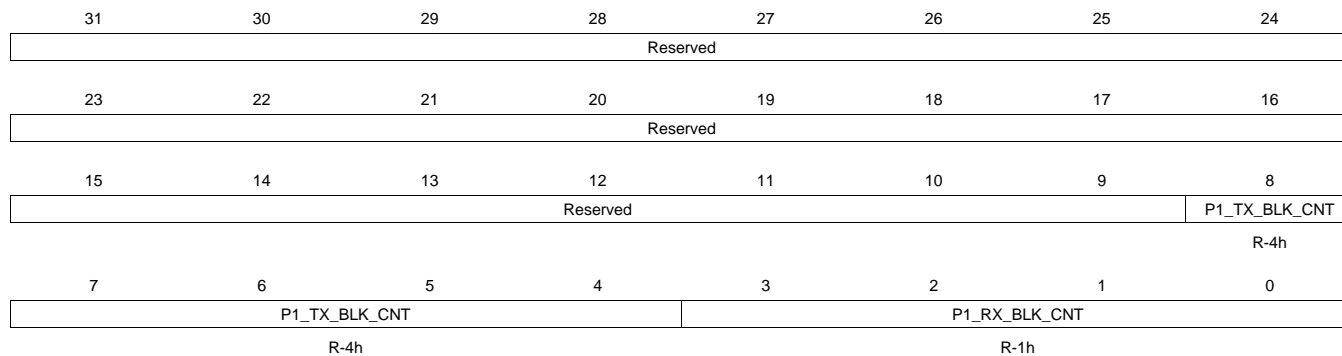

**Table 14-153. P1\_MAX\_BLKs Register Field Descriptions**

Bit	Field	Type	Reset	Description
8-4	P1_TX_MAX_BLKs	R/W	11h	Transmit FIFO Maximum Blocks - This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical transmit priority queues. 0x11 is the recommended value of p1_tx_max_blks unless the port is in full duplex flow control mode. In flow control mode, the p1_rx_max_blks will need to increase in order to accept the required run out in full duplex mode. This value will need to decrease by the amount of increase in p1_rx_max_blks. 0xe is the minimum value tx max blks.
3-0	P1_RX_MAX_BLKs	R/W	3h	Receive FIFO Maximum Blocks - This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical receive queue. This value must be greater than or equal to 0x3. It should be increased In full duplex flow control mode to 0x5 or 0x6 depending on the required runout space. The p1_tx_max_blks value must be decreased by the amount of increase in p1_rx_max_blks. 0x3 is the minimum value rx max blks and 0x6 is the maximum value.

**14.5.6.19 P1\_BLK\_CNT Register (offset = 10Ch) [reset = 41h]**

 P1\_BLK\_CNT is shown in [Figure 14-139](#) and described in [Table 14-154](#).

CPSW PORT 1 FIFO BLOCK USAGE COUNT (READ ONLY)

**Figure 14-139. P1\_BLK\_CNT Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-154. P1\_BLK\_CNT Register Field Descriptions**

Bit	Field	Type	Reset	Description
8-4	P1_TX_BLK_CNT	R	4h	Port 1 Transmit Block Count Usage - This value is the number of blocks allocated to the FIFO logical transmit queues.
3-0	P1_RX_BLK_CNT	R	1h	Port 1 Receive Block Count Usage - This value is the number of blocks allocated to the FIFO logical receive queues.

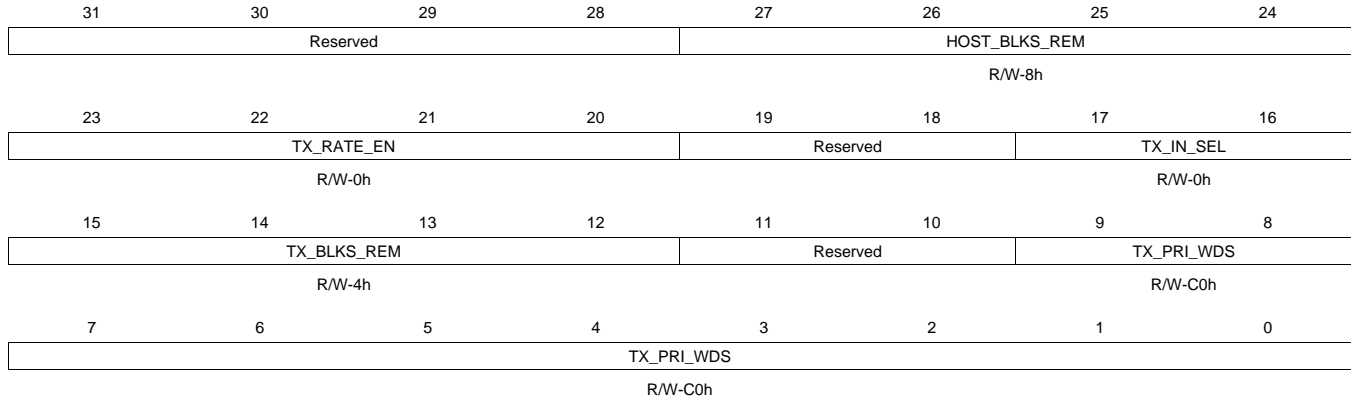

**14.5.6.20 P1\_TX\_IN\_CTL Register (offset = 110h) [reset = 80040C0h]**

P1\_TX\_IN\_CTL is shown in [Figure 14-140](#) and described in [Table 14-155](#).

CPSW PORT 1 TRANSMIT FIFO CONTROL

**Figure 14-140. P1\_TX\_IN\_CTL Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-155. P1\_TX\_IN\_CTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
27-24	HOST_BLKs_REM	R/W	8h	Transmit FIFO Blocks that must be free before a non rate-limited CPDMA channel can begin sending a packet to the FIFO.
23-20	TX_RATE_EN	R/W	0h	Transmit FIFO Input Rate Enable
17-16	TX_IN_SEL	R/W	0h	Transmit FIFO Input Queue Type Select 00 - Normal priority mode 01 - reserved 10 - Rate Limit mode 11 - reserved
15-12	TX_BLKs_REM	R/W	4h	Transmit FIFO Input Blocks to subtract in dual mac mode and blocks to subtract on non rate-limited traffic in rate-limit mode.
9-0	TX_PRI_WDS	R/W	C0h	Transmit FIFO Words in queue

**14.5.6.21 P1\_PORT\_VLAN Register (offset = 114h) [reset = 0h]**

 P1\_PORT\_VLAN is shown in [Figure 14-141](#) and described in [Table 14-156](#).

CPSW PORT 1 VLAN REGISTER

**Figure 14-141. P1\_PORT\_VLAN Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-170. P2\_CONTROL Register Field Descriptions**

Bit	Field	Type	Reset	Description
24	P2_PASS_PRI_TAGGED	R/W	0h	Port 2 Pass Priority Tagged 0 - Priority tagged packets have the zero VID replaced with the input port P2_PORT_VLAN [11:0] 1 - Priority tagged packets are processed unchanged.
21	P2_VLAN_LTYPE2_EN	R/W	0h	Port 2 VLAN LTYPE 2 enable 0 - disabled 1 - VLAN LTYPE2 enabled on transmit and receive
20	P2_VLAN_LTYPE1_EN	R/W	0h	Port 2 VLAN LTYPE 1 enable 0 - disabled 1 - VLAN LTYPE1 enabled on transmit and receive
16	P2_DSCP_PRI_EN	R/W	0h	Port 0 DSCP Priority Enable 0 - DSCP priority disabled 1 - DSCP priority enabled. All non-tagged IPV4 packets have their received packet priority determined by mapping the 6 TOS bits through the port DSCP priority mapping registers.
14	P2_TS_320	R/W	0h	Port 2 Time Sync Destination Port Number 320 enable 0 - disabled 1 - Annex D (UDP/IPv4) time sync packet destination port number 320 (decimal) is enabled.
13	P2_TS_319	R/W	0h	Port 2 Time Sync Destination Port Number 319 enable 0 - disabled 1 - Annex D (UDP/IPv4) time sync packet destination port number 319 (decimal) is enabled.
12	P2_TS_132	R/W	0h	Port 2 Time Sync Destination IP Address 132 enable 0 - disabled 1 - Annex D (UDP/IPv4) time sync packet destination IP address number 132 (decimal) is enabled.
11	P2_TS_131	R/W	0h	Port 2 Time Sync Destination IP Address 131 enable 0 - disabled 1 - Annex D (UDP/IPv4) time sync packet destination IP address number 131 (decimal) is enabled.

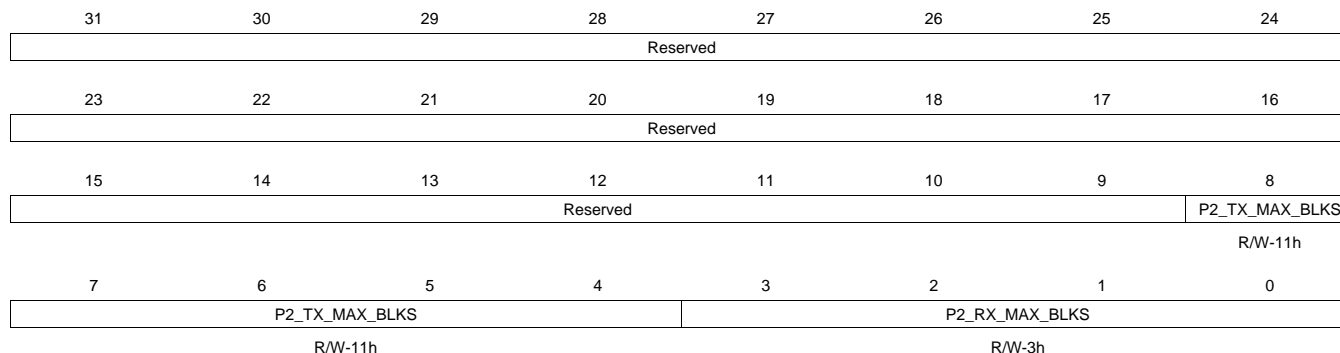

**Table 14-170. P2\_CONTROL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
10	P2_TS_130	R/W	0h	Port 2 Time Sync Destination IP Address 130 enable 0 - disabled 1 - Annex D (UDP/IPv4) time sync packet destination IP address number 130 (decimal) is enabled.
9	P2_TS_129	R/W	0h	Port 2 Time Sync Destination IP Address 129 enable 0 - disabled 1 - Annex D (UDP/IPv4) time sync packet destination IP address number 129 (decimal) is enabled.
8	P2_TS_TTL_NONZERO	R/W	0h	Port 2 Time Sync Time To Live Non-zero enable. 0 = TTL must be zero. 1 = TTL may be any value.
4	P2_TS_ANNEX_D_EN	R/W	0h	Port 2 Time Sync Annex D enable 0 - Annex D disabled 1 - Annex D enabled
3	P2_TS_LTYPE2_EN	R	0h	Port 2 Time Sync LTYPE 2 enable 0 - disabled 1 - enabled
2	P2_TS_LTYPE1_EN	R/W	0h	Port 2 Time Sync LTYPE 1 enable 0 - disabled 1 - enabled
1	P2_TS_TX_EN	R/W	0h	Port 2 Time Sync Transmit Enable 0 - disabled 1 - enabled
0	P2_TS_RX_EN	R/W	0h	Port 2 Time Sync Receive Enable 0 - Port 1 Receive Time Sync disabled 1 - Port 1 Receive Time Sync enabled

**14.5.6.36 P2\_MAX\_BLKs Register (offset = 208h) [reset = 113h]**

 P2\_MAX\_BLKs is shown in [Figure 14-156](#) and described in [Table 14-171](#).

CPSW PORT 2 MAXIMUM FIFO BLOCKS REGISTER

**Figure 14-156. P2\_MAX\_BLKs Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-171. P2\_MAX\_BLKs Register Field Descriptions**

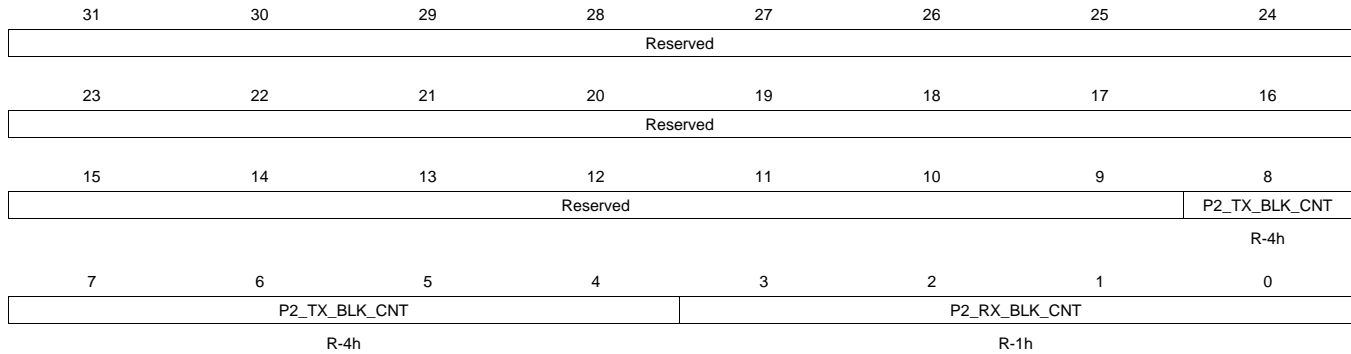

Bit	Field	Type	Reset	Description
8-4	P2_TX_MAX_BLKs	R/W	11h	Transmit FIFO Maximum Blocks - This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical transmit priority queues. 0x11 is the recommended value of p2_tx_max_blks unless the port is in fullduplex flow control mode. In flow control mode, the p2_rx_max_blks will need to increase in order to accept the required run out in fullduplex mode. This value will need to decrease by the amount of increase in p2_rx_max_blks. 0xe is the minimum value tx max blks.
3-0	P2_RX_MAX_BLKs	R/W	3h	Receive FIFO Maximum Blocks - This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical receive queue. This value must be greater than or equal to 0x3. It should be increased In fullduplex flow control mode to 0x5 or 0x6 depending on the required runout space. The p2_tx_max_blks value must be decreased by the amount of increase in p2_rx_max_blks. 0x3 is the minimum value rx max blks and 0x6 is the maximum value.

**14.5.6.37 P2\_BLK\_CNT Register (offset = 20Ch) [reset = 41h]**

P2\_BLK\_CNT is shown in [Figure 14-157](#) and described in [Table 14-172](#).

CPSW PORT 2 FIFO BLOCK USAGE COUNT (READ ONLY)

**Figure 14-157. P2\_BLK\_CNT Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

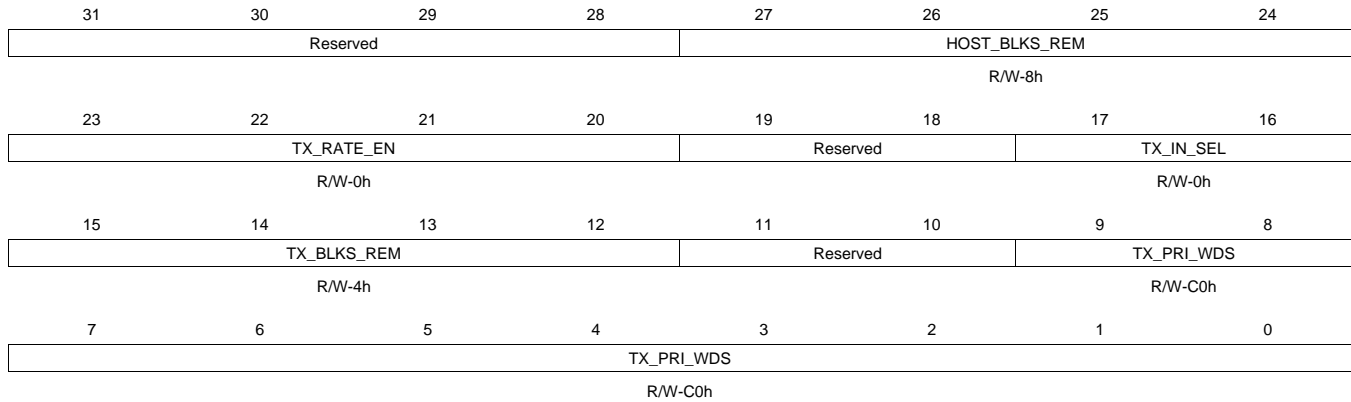

**Table 14-172. P2\_BLK\_CNT Register Field Descriptions**

Bit	Field	Type	Reset	Description
8-4	P2_TX_BLK_CNT	R	4h	Port 2 Transmit Block Count Usage - This value is the number of blocks allocated to the FIFO logical transmit queues.
3-0	P2_RX_BLK_CNT	R	1h	Port 2 Receive Block Count Usage - This value is the number of blocks allocated to the FIFO logical receive queues.

**14.5.6.38 P2\_TX\_IN\_CTL Register (offset = 210h) [reset = 80040C0h]**

 P2\_TX\_IN\_CTL is shown in [Figure 14-158](#) and described in [Table 14-173](#).

CPSW PORT 2 TRANSMIT FIFO CONTROL

**Figure 14-158. P2\_TX\_IN\_CTL Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-173. P2\_TX\_IN\_CTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
27-24	HOST_BLKs_REM	R/W	8h	Transmit FIFO Blocks that must be free before a non rate-limited CPDMA channel can begin sending a packet to the FIFO.
23-20	TX_RATE_EN	R/W	0h	Transmit FIFO Input Rate Enable
17-16	TX_IN_SEL	R/W	0h	Transmit FIFO Input Queue Type Select 00 - Normal priority mode 01 - reserved 10 - Rate Limit mode 11 - reserved
15-12	TX_BLKs_REM	R/W	4h	Transmit FIFO Input Blocks to subtract in dual mac mode and blocks to subtract on non rate-limited traffic in rate-limit mode.
9-0	TX_PRI_WDS	R/W	C0h	Transmit FIFO Words in queue

**14.5.6.39 P2\_PORT\_VLAN Register (offset = 214h) [reset = 0h]**

P2\_PORT\_VLAN is shown in [Figure 14-159](#) and described in [Table 14-174](#).

1-0	PRI0	R/W	1h	Priority 0 - A packet header priority of 0x0 is given this switch queue pri.

**14.5.6.41 P2\_TS\_SEQ\_MTYPE Register (offset = 21Ch) [reset = 1E000h]**

P2\_TS\_SEQ\_MTYPE is shown in [Figure 14-161](#) and described in [Table 14-176](#).

CPSW\_3GF PORT 2 TIME SYNC SEQUENCE ID OFFSET AND MSG TYPE.

**Figure 14-161. P2\_TS\_SEQ\_MTYPE Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

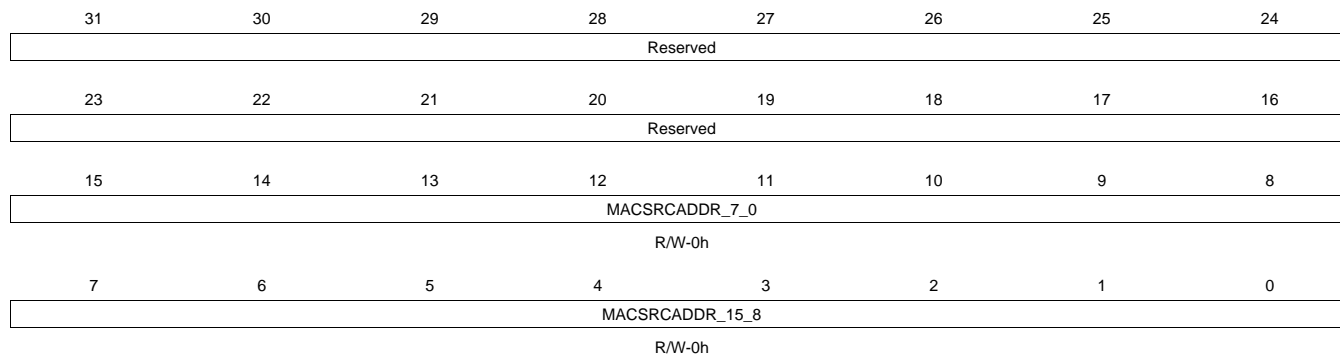

**Table 14-176. P2\_TS\_SEQ\_MTYPE Register Field Descriptions**

Bit	Field	Type	Reset	Description
21-16	P2_TS_SEQ_ID_OFFSET	R/W	1Eh	Port 2 Time Sync Sequence ID Offset This is the number of octets that the sequence ID is offset in the tx and rx time sync message header. The minimum value is 6.
15-0	P2_TS_MSG_TYPE_EN	R/W	0h	Port 2 Time Sync Message Type Enable - Each bit in this field enables the corresponding message type in receive and transmit time sync messages (Bit 0 enables message type 0 etc.).

**14.5.6.42 P2\_SA\_LO Register (offset = 220h) [reset = 0h]**

 P2\_SA\_LO is shown in [Figure 14-162](#) and described in [Table 14-177](#).

CPSW CPGMAC\_SL2 SOURCE ADDRESS LOW REGISTER

**Figure 14-162. P2\_SA\_LO Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-177. P2\_SA\_LO Register Field Descriptions**

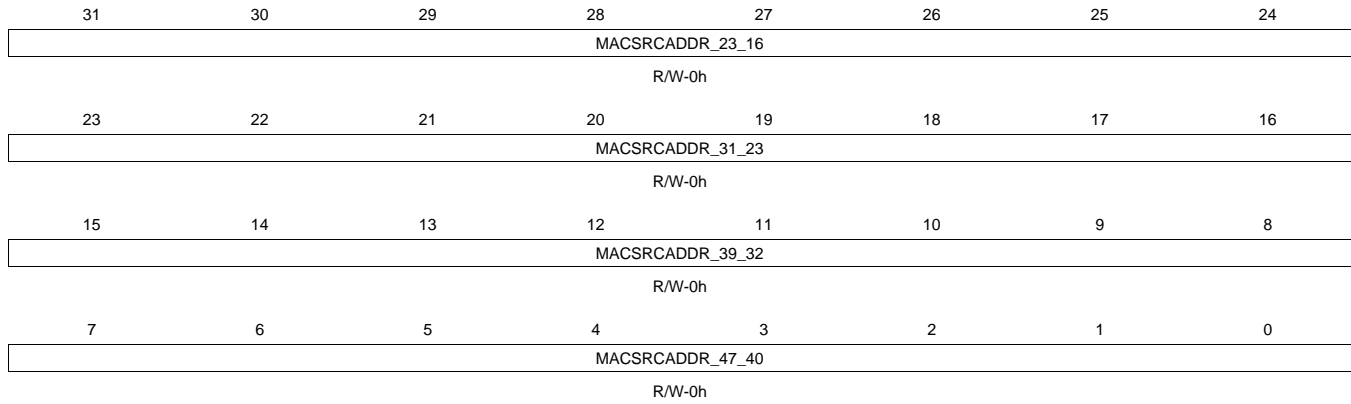

Bit	Field	Type	Reset	Description
15-8	MACSRCADDR_7_0	R/W	0h	Source Address Lower 8 bits (byte 0)
7-0	MACSRCADDR_15_8	R/W	0h	Source Address bits 15:8 (byte 1)

**14.5.6.43 P2\_SA\_HI Register (offset = 224h) [reset = 0h]**

 P2\_SA\_HI is shown in [Figure 14-163](#) and described in [Table 14-178](#).

CPSW CPGMAC\_SL2 SOURCE ADDRESS HIGH REGISTER

**Figure 14-163. P2\_SA\_HI Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-178. P2\_SA\_HI Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	MACSRCADDR_23_16	R/W	0h	Source Address bits 23:16 (byte 2)
23-16	MACSRCADDR_31_23	R/W	0h	Source Address bits 31:23 (byte 3)
15-8	MACSRCADDR_39_32	R/W	0h	Source Address bits 39:32 (byte 4)
7-0	MACSRCADDR_47_40	R/W	0h	Source Address bits 47:40 (byte 5)

**14.5.6.44 P2\_SEND\_PERCENT Register (offset = 228h) [reset = 0h]**

 P2\_SEND\_PERCENT is shown in [Figure 14-164](#) and described in [Table 14-179](#).

CPSW PORT 2 TRANSMIT QUEUE SEND PERCENTAGES

**Figure 14-164. P2\_SEND\_PERCENT Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-179. P2\_SEND\_PERCENT Register Field Descriptions**

Bit	Field	Type	Reset	Description
22-16	PRI3_SEND_PERCENT	R/W	0h	Priority 3 Transmit Percentage - This percentage value is sent from FIFO priority 3 (maximum) when the p1_pri3_shape_en is set (queue shaping enabled). This is the percentage of the wire that packets from priority 3 receive (which includes interpacket gap and preamble bytes). If shaping is enabled on this queue then this value must be between zero and 0d100 (not inclusive).
14-8	PRI2_SEND_PERCENT	R/W	0h	Priority 2 Transmit Percentage - This percentage value is sent from FIFO priority 2 (maximum) when the p1_pri2_shape_en is set (queue shaping enabled). This is the percentage of the wire that packets from priority 2 receive (which includes interpacket gap and preamble bytes). If shaping is enabled on this queue then this value must be between zero and 0d100 (not inclusive).
6-0	PRI1_SEND_PERCENT	R/W	0h	Priority 1 Transmit Percentage - This percentage value is sent from FIFO priority 1 (maximum) when the p1_pri1_shape_en is set (queue shaping enabled). This is the percentage of the wire that packets from priority 1 receive (which includes interpacket gap and preamble bytes). If shaping is enabled on this queue then this value must be between zero and 0d100 (not inclusive).

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-190. MACCONTROL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-25	Reserved	R	0h	
24	RX_CMF_EN	R/W	0h	RX Copy MAC Control Frames Enable - Enables MAC control frames to be transferred to memory. MAC control frames are normally acted upon (if enabled), but not copied to memory. MAC control frames that are pause frames will be acted upon if enabled in the MacControl register, regardless of the value of rx_cmf_en. Frames transferred to memory due to rx_cmf_en will have the control bit set in their EOP buffer descriptor. 0 - MAC control frames are filtered (but acted upon if enabled). 1 - MAC control frames are transferred to memory.
23	RX_CSF_EN	R/W	0h	RX Copy Short Frames Enable - Enables frames or fragments shorter than 64 bytes to be copied to memory. Frames transferred to memory due to rx_csf_en will have the fragment or undersized bit set in their receive footer. Fragments are short frames that contain CRC/align/code errors and undersized are short frames without errors. 0 - Short frames are filtered 1 - Short frames are transferred to memory.
22	RX_CEF_EN	R/W	0h	RX Copy Error Frames Enable - Enables frames containing errors to be transferred to memory. The appropriate error bit will be set in the frame receive footer. Frames containing errors will be filtered when rx_cef_en is not set. 0 - Frames containing errors are filtered. 1 - Frames containing errors are transferred to memory.
21	TX_SHORT_GAP_LIM_EN	R/W	0h	Transmit Short Gap Limit Enable When set this bit limits the number of short gap packets transmitted to 100ppm. Each time a short gap packet is sent, a counter is loaded with 10,000 and decremented on each wireside clock. Another short gap packet will not be sent out until the counter decrements to zero. This mode is included to preclude the host from filling up the FIFO and sending every packet out with short gap which would violate the maximum number of packets per second allowed.
20-19	Reserved	R	0h	

**Table 14-190. MACCONTROL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
18	EXT_EN	R/W	0h	Mode of operation. 0 - Forced mode of operation. 1 - In-band mode of operation.
17	GIG_FORCE	R/W	0h	Gigabit Mode Force - This bit is used to force the CPGMAC_SL into gigabit mode if the input GMII_MTCLK has been stopped by the PHY.
16	IFCTL_B	R/W	0h	Connects to the speed_in input of the respective RMII gasket. When using RMII mode: 0 - 10Mbps operation 1 - 100Mbps operation
15	IFCTL_A	R/W	0h	Connects to the speed_in input of the respective RMII gasket. When using RMII mode: 0 - 10Mbps operation 1 - 100Mbps operation
14-12	Reserved	R	0h	
11	CMD_IDLE	R/W	0h	Command Idle 0 - Idle not commanded 1 - Idle Commanded (read idle in MacStatus)
10	TX_SHORT_GAP_EN	R/W	0h	Transmit Short Gap Enable 0 - Transmit with a short IPG is disabled 1 - Transmit with a short IPG (when TX_SHORT_GAP input is asserted) is enabled.
9-8	Reserved	R	0h	
7	GIG	R/W	0h	Gigabit Mode - 0 - 10/100 mode 1 - Gigabit mode (full duplex only) The GIG_OUT output is the value of this bit.
6	TX_PACE	R/W	0h	Transmit Pacing Enable 0 - Transmit Pacing Disabled 1 - Transmit Pacing Enabled
5	GMII_EN	R/W	0h	GMII Enable - 0 - GMII RX and TX held in reset. 1 - GMII RX and TX released from reset.
4	TX_FLOW_EN	R/W	0h	Transmit Flow Control Enable - Determines if incoming pause frames are acted upon in full-duplex mode. Incoming pause frames are not acted upon in half-duplex mode regardless of this bit setting. The RX_MBP_Enable bits determine whether or not received pause frames are transferred to memory. 0 - Transmit Flow Control Disabled. Full-duplex mode - Incoming pause frames are not acted upon. 1 - Transmit Flow Control Enabled . Full-duplex mode - Incoming pause frames are acted upon.
3	RX_FLOW_EN	R/W	0h	Receive Flow Control Enable - 0 - Receive Flow Control Disabled Half-duplex mode - No flow control generated collisions are sent. Full-duplex mode - No outgoing pause frames are sent. 1 - Receive Flow Control Enabled Half-duplex mode - Collisions are initiated when receive flow control is triggered. Full-duplex mode - Outgoing pause frames are sent when receive flow control is triggered.
2	MTEST	R/W	0h	Manufacturing Test mode - This bit must be set to allow writes to the Backoff_Test and PauseTimer registers.
1	LOOPBACK	R/W	0h	Loop Back Mode - Loopback mode forces internal fullduplex mode regardless of whether the fullduplex bit is set or not. The loopback bit should be changed only when GMII_en is deasserted. 0 - Not looped back 1 - Loop Back Mode enabled

**Table 14-190. MACCONTROL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	FULLDUPLEX	R/W	0h	Full Duplex mode - Gigabit mode forces fullduplex mode regardless of whether the fullduplex bit is set or not. The FULLDUPLEX_OUT output is the value of this register bit 0 - half duplex mode 1 - full duplex mode

**14.5.7.3 MACSTATUS Register (offset = 8h) [reset = 0h]**

 MACSTATUS is shown in [Figure 14-175](#) and described in [Table 14-191](#).

CPGMAC\_SL MAC STATUS REGISTER

**Figure 14-175. MACSTATUS Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-191. MACSTATUS Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	IDLE	R	0h	CPGMAC_SL IDLE - The CPGMAC_SL is in the idle state (valid after an idle command) 0 - The CPGMAC_SL is not in the idle state. 1 - The CPGMAC_SL is in the idle state.
30-5	Reserved	R	0h	
4	EXT_GIG	R	0h	External GIG - This is the value of the EXT_GIG input bit.
3	EXT_FULLLDUPLEX	R	0h	External Fullduplex - This is the value of the EXT_FULLLDUPLEX input bit.
2	Reserved	R	0h	
1	RX_FLOW_ACT	R	0h	Receive Flow Control Active - When asserted, indicates that receive flow control is enabled and triggered.
0	TX_FLOW_ACT	R	0h	Transmit Flow Control Active - When asserted, this bit indicates that the pause time period is being observed for a received pause frame. No new transmissions will begin while this bit is asserted except for the transmission of pause frames. Any transmission in progress when this bit is asserted will complete.

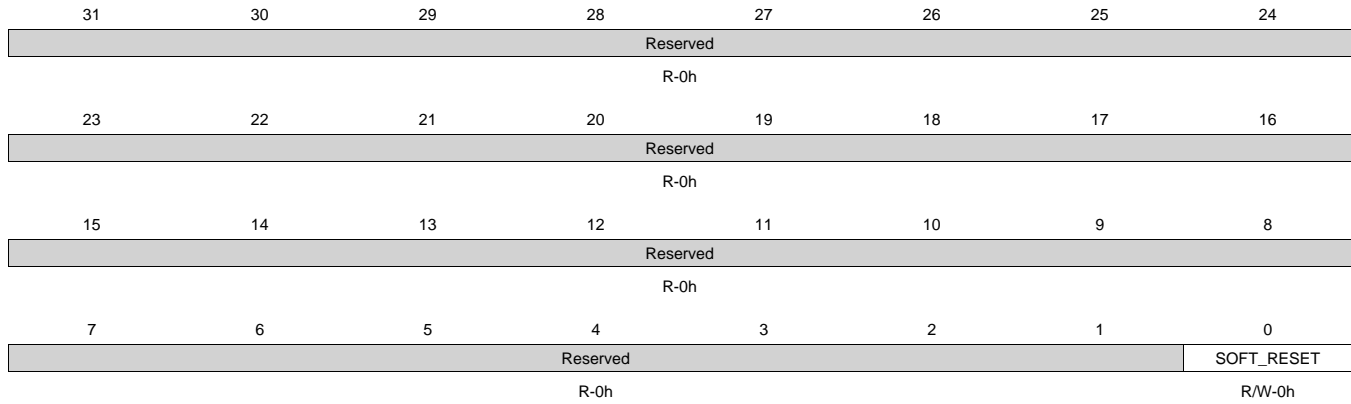

#### 14.5.7.4 SOFT\_RESET Register (offset = Ch) [reset = 0h]

SOFT\_RESET is shown in [Figure 14-176](#) and described in [Table 14-192](#).

CPGMAC\_SL SOFT RESET REGISTER

**Figure 14-176. SOFT\_RESET Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

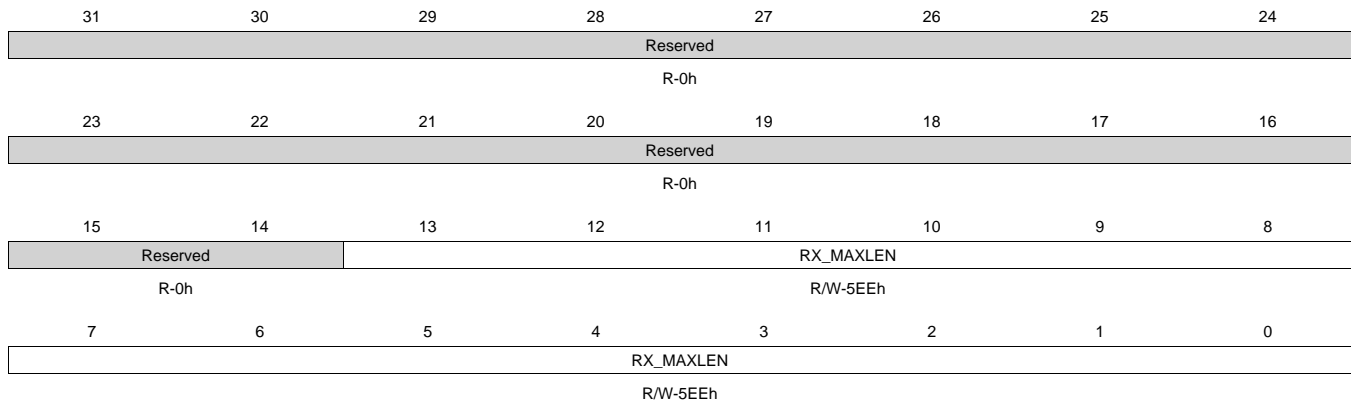

**Table 14-192. SOFT\_RESET Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	Reserved	R	0h	
0	SOFT_RESET	R/W	0h	Software reset - Writing a one to this bit causes the CPGMAC_SL logic to be reset. After writing a one to this bit, it may be polled to determine if the reset has occurred. If a one is read, the reset has not yet occurred. If a zero is read then reset has occurred.

**14.5.7.5 RX\_MAXLEN Register (offset = 10h) [reset = 5EEh]**

 RX\_MAXLEN is shown in [Figure 14-177](#) and described in [Table 14-193](#).

CPGMAC\_SL RX MAXIMUM LENGTH REGISTER

**Figure 14-177. RX\_MAXLEN Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-193. RX\_MAXLEN Register Field Descriptions**

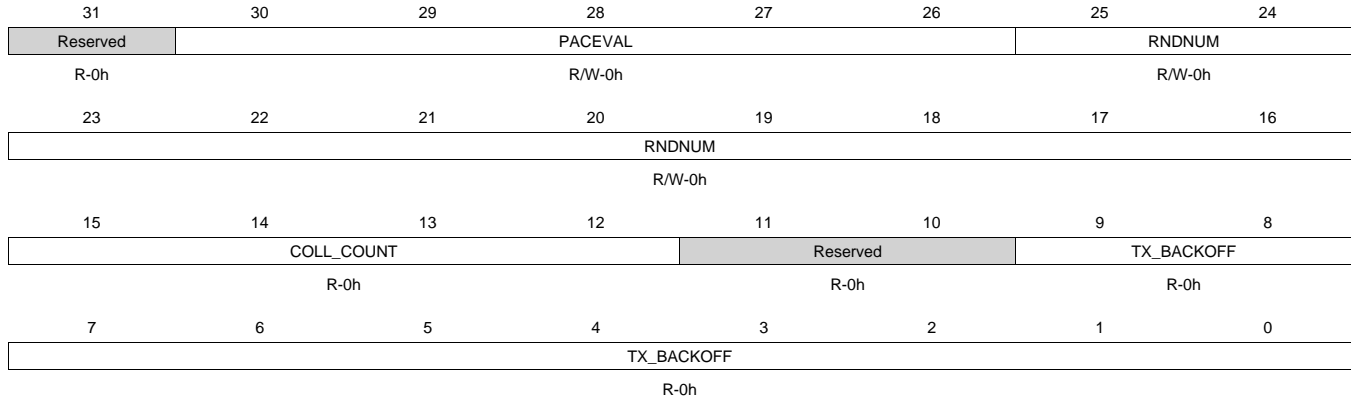

Bit	Field	Type	Reset	Description
31-14	Reserved	R	0h	
13-0	RX_MAXLEN	R/W	5EEh	RX Maximum Frame Length - This field determines the maximum length of a received frame. The reset value is 1518 (dec). Frames with byte counts greater than rx_maxlen are long frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment error are jabber frames. The maximum value is 16,383.

### 14.5.7.6 BOFFTEST Register (offset = 14h) [reset = 0h]

BOFFTEST is shown in [Figure 14-178](#) and described in [Table 14-194](#).

CPGMAC\_SL BACKOFF TEST REGISTER

**Figure 14-178. BOFFTEST Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

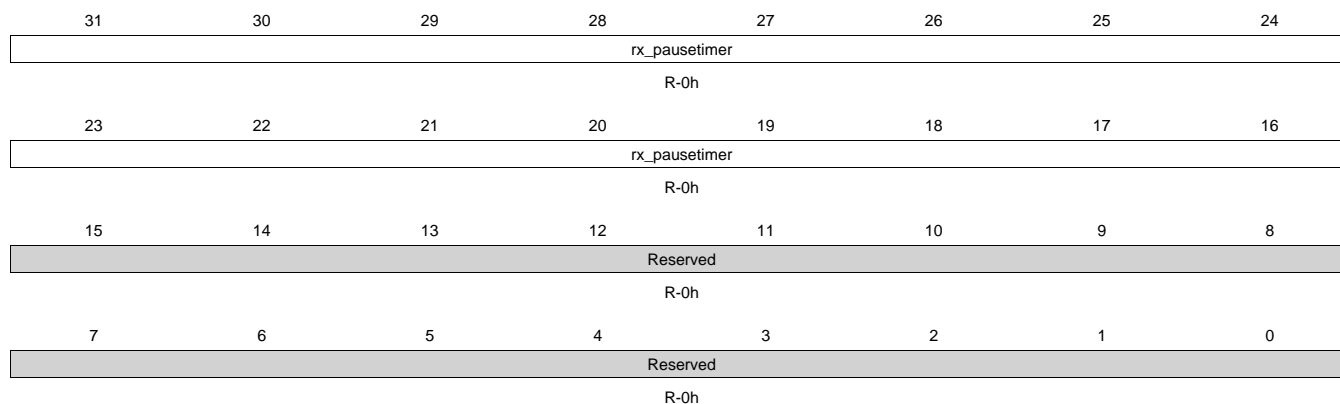

**Table 14-194. BOFFTEST Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	Reserved	R	0h	
30-26	PACEVAL	R/W	0h	Pacing Register Current Value. A non-zero value in this field indicates that transmit pacing is active. A transmit frame collision or deferral causes paceval to loaded with decimal 31, good frame transmissions (with no collisions or deferrals) cause paceval to be decremented down to zero. When paceval is nonzero, the transmitter delays 4 IPGs between new frame transmissions after each successfully transmitted frame that had no deferrals or collisions. Transmit pacing helps reduce "capture" effects improving overall network bandwidth.
25-16	RNDNUM	R/W	0h	Backoff Random Number Generator - This field allows the Backoff Random Number Generator to be read (or written in test mode only). This field can be written only when mtest has previously been set. Reading this field returns the generator's current value. The value is reset to zero and begins counting on the clock after the deassertion of reset.
15-12	COLL_COUNT	R	0h	Collision Count - The number of collisions the current frame has experienced.
11-10	Reserved	R	0h	
9-0	TX_BACKOFF	R	0h	Backoff Count - This field allows the current value of the backoff counter to be observed for test purposes. This field is loaded automatically according to the backoff algorithm, and is decremented by one for each slot time after the collision.

**14.5.7.7 RX\_PAUSE Register (offset = 18h) [reset = 0h]**

 RX\_PAUSE is shown in [Figure 14-179](#) and described in [Table 14-195](#).

CPGMAC\_SL RECEIVE PAUSE TIMER REGISTER

**Figure 14-179. RX\_PAUSE Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

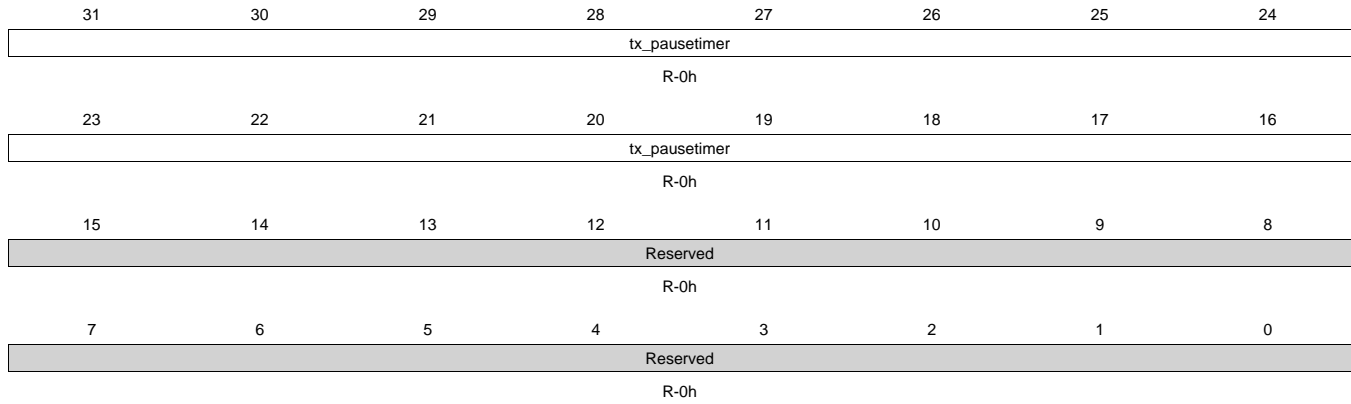

**Table 14-195. RX\_PAUSE Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	rx_pausetimer	R	0h	RX Pause Timer Value - This field allows the contents of the receive pause timer to be observed (and written in test mode). The receive pause timer is loaded with 0xFF00 when the CPGMAC_SL sends an outgoing pause frame (with pause time of 0xFFFF). The receive pause timer is decremented at slot time intervals. If the receive pause timer decrements to zero, then another outgoing pause frame will be sent and the load/decrement process will be repeated.
15-0	Reserved	R	0h	

**14.5.7.8 TX\_PAUSE Register (offset = 1Ch) [reset = 0h]**

 TX\_PAUSE is shown in [Figure 14-180](#) and described in [Table 14-196](#).

CPGMAC\_SL TRANSMIT PAUSE TIMER REGISTER

**Figure 14-180. TX\_PAUSE Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

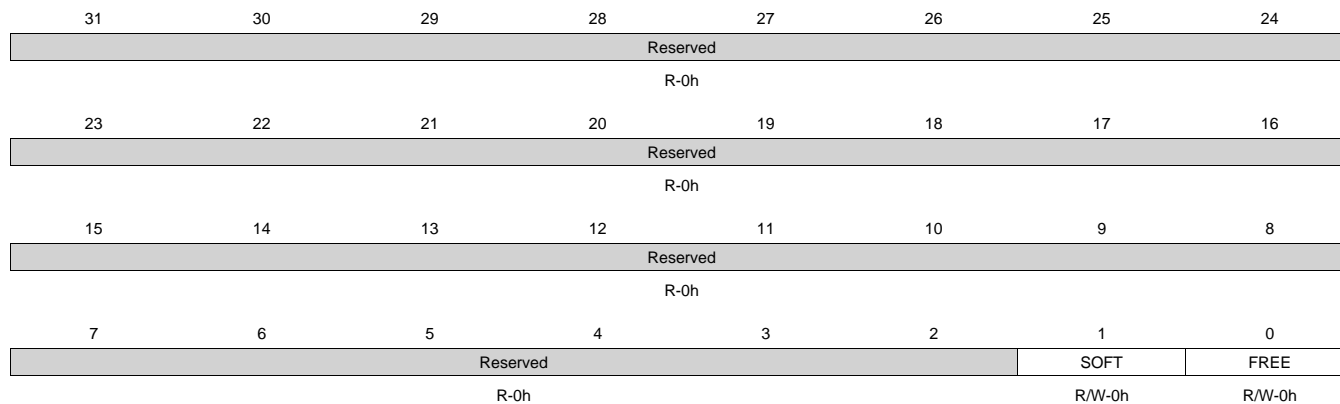

**Table 14-196. TX\_PAUSE Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	tx_pausetimer	R	0h	TX Pause Timer Value - This field allows the contents of the transmit pause timer to be observed (and written in test mode). The transmit pause timer is loaded by a received (incoming) pause frame, and then decremented, at slottime intervals, down to zero at which time CPGMAC_SL transmit frames are again enabled.
15-0	Reserved	R	0h	

**14.5.7.9 EMCONTROL Register (offset = 20h) [reset = 0h]**

 EMCONTROL is shown in [Figure 14-181](#) and described in [Table 14-197](#).

CPGMAC\_SL EMULATION CONTROL REGISTER

**Figure 14-181. EMCONTROL Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

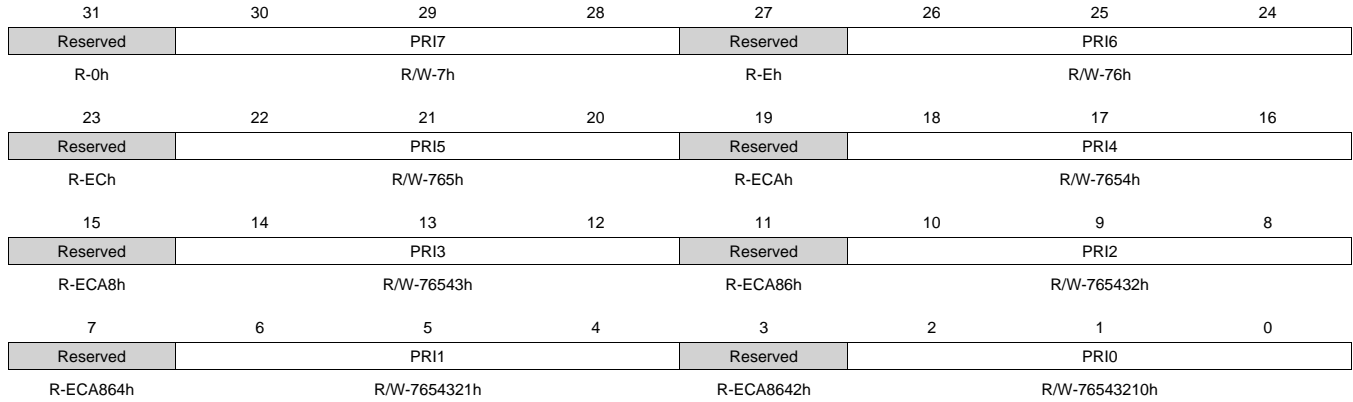

**Table 14-197. EMCONTROL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	Reserved	R	0h	
1	SOFT	R/W	0h	Emulation Soft Bit
0	FREE	R/W	0h	Emulation Free Bit

**14.5.7.10 RX\_PRI\_MAP Register (offset = 24h) [reset = 76543210h]**

 RX\_PRI\_MAP is shown in [Figure 14-182](#) and described in [Table 14-198](#).

CPGMAC\_SL RX PKT PRIORITY TO HEADER PRIORITY MAPPING REGISTER

**Figure 14-182. RX\_PRI\_MAP Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCi = Write 1 to clear bit; -n = value after reset

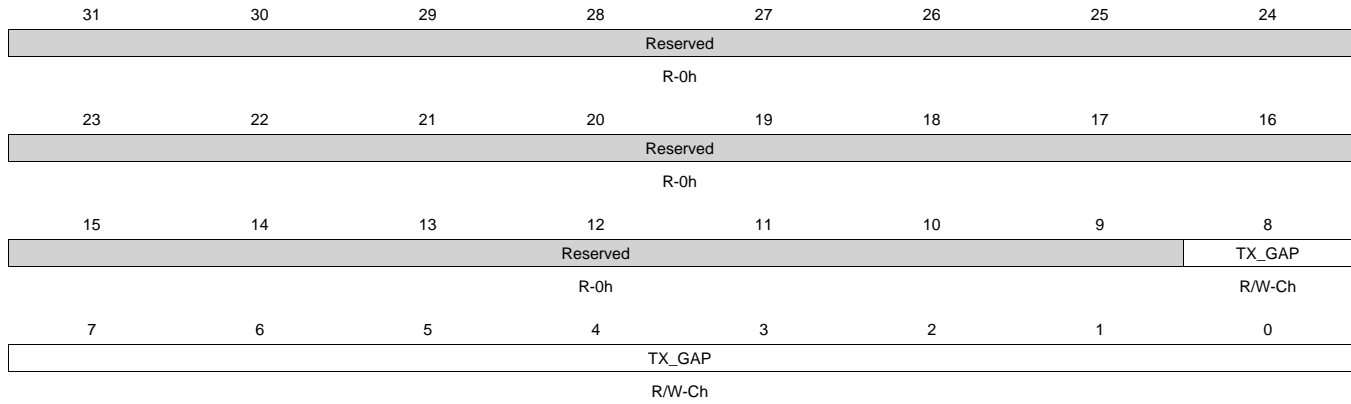

**Table 14-198. RX\_PRI\_MAP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	Reserved	R	0h	
30-28	PRI7	R/W	7h	Priority 7 - A packet priority of 0x7 is mapped (changed) to this value.
27	Reserved	R	Eh	
26-24	PRI6	R/W	76h	Priority 6 - A packet priority of 0x6 is mapped (changed) to this value.
23	Reserved	R	ECh	
22-20	PRI5	R/W	765h	Priority 5 - A packet priority of 0x5 is mapped (changed) to this value.
19	Reserved	R	ECAh	
18-16	PRI4	R/W	7654h	Priority 4 - A packet priority of 0x4 is mapped (changed) to this value.
15	Reserved	R	ECA8h	
14-12	PRI3	R/W	76543h	Priority 3 - A packet priority of 0x3 is mapped (changed) to this value.
11	Reserved	R	ECA86h	
10-8	PRI2	R/W	765432h	Priority 2 - A packet priority of 0x2 is mapped (changed) to this value.
7	Reserved	R	ECA864h	
6-4	PRI1	R/W	7654321h	Priority 1 - A packet priority of 0x1 is mapped (changed) to this value.
3	Reserved	R	ECA8642h	
2-0	PRI0	R/W	76543210h	Priority 0 - A packet priority of 0x0 is mapped (changed) to this value.

**14.5.7.11 TX\_GAP Register (offset = 28h) [reset = Ch]**

TX\_GAP is shown in [Figure 14-183](#) and described in [Table 14-199](#).

TRANSMIT INTER-PACKET GAP REGISTER

**Figure 14-183. TX\_GAP Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-199. TX\_GAP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-9	Reserved	R	0h	
8-0	TX_GAP	R/W	Ch	Transmit Inter-Packet Gap

**14.5.8 CPSW\_SS Registers**

[Table 14-200](#) lists the memory-mapped registers for the CPSW\_SS. All register offset addresses not listed in [Table 14-200](#) should be considered as reserved locations and the register contents should not be modified.

**Table 14-200. CPSW\_SS REGISTERS**

Offset	Acronym	Register Name	Section
0h	ID_VER	ID VERSION REGISTER	<a href="#">Section 14.5.8.1</a>
4h	CONTROL	SWITCH CONTROL REGISTER	<a href="#">Section 14.5.8.2</a>

23	22	21	20	19	18	17	16
Reserved							
15	14	13	12	11	10	9	8
Reserved							
7	6	5	4	3	2	1	0
Reserved				DLR_EN	RX_VLAN_ENCAP	VLAN_AWARE	FIFO_LOOPBACK
				R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-202. CONTROL Register Field Descriptions**

Bit	Field	Type	Reset	Description
3	DLR_EN	R/W-0	0	DLR enable 0 - DLR is disabled. DLR packets will not be moved to queue priority 3 and will not be separated out onto dlr_cpdma_ch. 1 - DLR is disabled. DLR packets be moved to destination port transmit queue priority 3 and will be separated out onto dlr_cpdma_ch when packet is to egress on port 0.
2	RX_VLAN_ENCAP	R/W-0	0	Port 0 VLAN Encapsulation (egress): 0 - Port 2 receive packets (from 3G) are not VLAN encapsulated. 1 - Port 2 receive packets (from 3G) are VLAN encapsulated.
1	VLAN_AWARE	R/W-0	0	VLAN Aware Mode: 0 - 3G is in the VLAN unaware mode. 1 - 3G is in the VLAN aware mode.
0	FIFO_LOOPBACK	R/W-0	0	FIFO Loopback Mode 0 - Loopback is disabled 1 - FIFO Loopback mode enabled. Each packet received is turned around and sent out on the same port's transmit path. Port 2 receive is fixed on channel zero. The RXSOFOVERRUN statistic will increment for every packet sent in FIFO loopback mode.

**14.5.8.3 SOFT\_RESET Register (offset = 8h) [reset = 0h]**

SOFT\_RESET is shown in [Figure 14-186](#) and described in [Table 14-203](#).

SOFT RESET REGISTER

**Figure 14-186. SOFT\_RESET Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-203. SOFT\_RESET Register Field Descriptions**

Bit	Field	Type	Reset	Description
0	SOFT_RESET	R/W-0	0	Software reset - Writing a one to this bit causes the 3G logic to be reset. After writing a one to this bit, it may be polled to determine if the reset has occurred. If a one is read, the reset has not yet occurred. If a zero is read then reset has occurred.

**14.5.8.4 STAT\_PORT\_EN Register (offset = Ch) [reset = 0h]**

 STAT\_PORT\_EN is shown in [Figure 14-187](#) and described in [Table 14-204](#).

STATISTICS PORT ENABLE REGISTER

Reserved					P2_PTYPE_ESC	P1_PTYPE_ESC	P0_PTYPE_ESC
					R/W-0	R/W-0	R/W-0
7	6	5	4	3	2	1	0
Reserved				ESC_PRI_LD_VAL			
				R/W-0			

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-205. PTYPE Register Field Descriptions**

Bit	Field	Type	Reset	Description
21	P2_PRI3_SHAPE_EN	R/W-0	0	Port 2 Queue Priority 3 Transmit Shape Enable - If there is only one shaping queue then it must be priority 3.
20	P2_PRI2_SHAPE_EN	R/W-0	0	Port 2 Queue Priority 2 Transmit Shape Enable - If there are two shaping queues then they must be priorities 3 and 2.
19	P2_PRI1_SHAPE_EN	R/W-0	0	Port 2 Queue Priority 1 Transmit Shape Enable - If there are three shaping queues all three bits should be set.
18	P1_PRI3_SHAPE_EN	R/W-0	0	Port 1 Queue Priority 3 Transmit Shape Enable - If there is only one shaping queue then it must be priority 3.
17	P1_PRI2_SHAPE_EN	R/W-0	0	Port 1 Queue Priority 2 Transmit Shape Enable- If there are two shaping queues then they must be priorities 3 and 2.
16	P1_PRI1_SHAPE_EN	R/W-0	0	Port 1 Queue Priority 1 Transmit Shape Enable- If there are three shaping queues all three bits should be set.
10	P2_PTYPE_ESC	R/W-0	0	Port 2 Priority Type Escalate - 0 - Port 2 priority type fixed 1 - Port 2 priority type escalate Escalate should not be used with queue shaping.
9	P1_PTYPE_ESC	R/W-0	0	Port 1 Priority Type Escalate - 0 - Port 1 priority type fixed 1 - Port 1 priority type escalate Escalate should not be used with queue shaping.
8	P0_PTYPE_ESC	R/W-0	0	Port 0 Priority Type Escalate - 0 - Port 0 priority type fixed 1 - Port 0 priority type escalate Escalate should not be used with queue shaping.
4-0	ESC_PRI_LD_VAL	R/W-0	0	Escalate Priority Load Value When a port is in escalate priority, this is the number of higher priority packets sent before the next lower priority is allowed to send a packet. Escalate priority allows lower priority packets to be sent at a fixed rate relative to the next higher priority.

### 14.5.8.6 SOFT\_IDLE Register (offset = 14h) [reset = 0h]

SOFT\_IDLE is shown in [Figure 14-189](#) and described in [Table 14-206](#).

SOFTWARE IDLE

**Figure 14-189. SOFT\_IDLE Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-206. SOFT\_IDLE Register Field Descriptions**

Bit	Field	Type	Reset	Description
0	SOFT_IDLE	R/W-0	0	Software Idle - Setting this bit causes the switch fabric to stop forwarding packets at the next start of packet.

**14.5.8.7 THRU\_RATE Register (offset = 18h) [reset = 3003h]**

THRU\_RATE is shown in [Figure 14-190](#) and described in [Table 14-207](#).

THROUGHPUT RATE

**Figure 14-190. THRU\_RATE Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-207. THRU\_RATE Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-12	SL_RX_THRU_RATE	R/W-0	0	CPGMAC_SL Switch FIFO receive through rate. This register value is the maximum throughput of the ethernet ports to the crossbar SCR. The default is one 8-byte word for every 3 CLK periods maximum.
3-0	CPDMA_THRU_RATE	R/W-0	0	CPDMA Switch FIFO receive through rate. This register value is the maximum throughput of the CPDMA host port to the crossbar SCR. The default is one 8-byte word for every 3 CLK periods maximum.

**14.5.8.8 GAP\_THRESH Register (offset = 1Ch) [reset = Bh]**

GAP\_THRESH is shown in [Figure 14-191](#) and described in [Table 14-208](#).

CPGMAC\_SL SHORT GAP THRESHOLD

**Figure 14-191. GAP\_THRESH Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-208. GAP\_THRESH Register Field Descriptions**

Bit	Field	Type	Reset	Description
4-0	GAP_THRESH	R/W-0	0	CPGMAC_SL Short Gap Threshold - This is the CPGMAC_SL associated FIFO transmit block usage value for triggering TX_SHORT_GAP.

**14.5.8.9 TX\_START\_WDS Register (offset = 20h) [reset = 20h]**

TX\_START\_WDS is shown in [Figure 14-192](#) and described in [Table 14-209](#).

TRANSMIT START WORDS

**Figure 14-192. TX\_START\_WDS Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

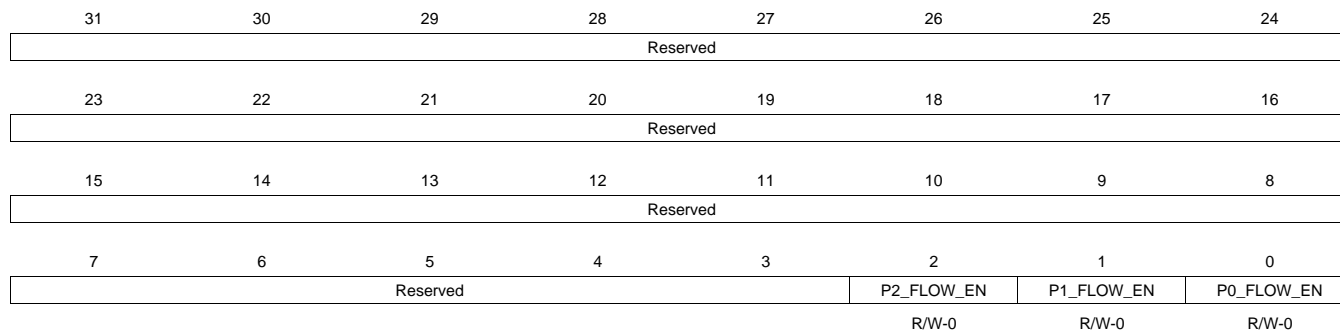

**Table 14-209. TX\_START\_WDS Register Field Descriptions**

Bit	Field	Type	Reset	Description
10-0	TX_START_WDS	R/W-0	0	FIFO Packet Transmit (egress) Start Words. This value is the number of required packet words in the transmit FIFO before the packet egress will begin. This value is non-zero to preclude underrun. Decimal 32 is the recommended value. It should not be increased unnecessarily to prevent adding to the switch latency.

**14.5.8.10 FLOW\_CONTROL Register (offset = 24h) [reset = 1h]**

 FLOW\_CONTROL is shown in [Figure 14-193](#) and described in [Table 14-210](#).

FLOW CONTROL

**Figure 14-193. FLOW\_CONTROL Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-210. FLOW\_CONTROL Register Field Descriptions**

Bit	Field	Type	Reset	Description
2	P2_FLOW_EN	R/W-0	0	Port 2 Receive flow control enable
1	P1_FLOW_EN	R/W-0	0	Port 1 Receive flow control enable
0	P0_FLOW_EN	R/W-0	0	Port 0 Receive flow control enable

**14.5.8.11 VLAN\_LTYPE Register (offset = 28h) [reset = 81008100h]**

 VLAN\_LTYPE is shown in [Figure 14-194](#) and described in [Table 14-211](#).

LTYPE1 AND LTYPE 2 REGISTER

**Figure 14-194. VLAN\_LTYPE Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-211. VLAN\_LTYPE Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	VLAN_LTYPE2	R/W-0	0	Time Sync VLAN LTYPE2 This VLAN LTYPE value is used for tx and rx. This is the inner VLAN if both are present.
15-0	VLAN_LTYPE1	R/W-0	0	Time Sync VLAN LTYPE1 This VLAN LTYPE value is used for tx and rx. This is the outer VLAN if both are present.

**14.5.8.12 TS\_LTYPE Register (offset = 2Ch) [reset = 0h]**

 TS\_LTYPE is shown in [Figure 14-195](#) and described in [Table 14-212](#).

**VLAN\_LTYPE1 AND VLAN\_LTYPE2 REGISTER**
**Figure 14-195. TS\_LTYPE Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-212. TS\_LTYPE Register Field Descriptions**

Bit	Field	Type	Reset	Description
21-16	TS_LTYPE2	R/W-0	0	Time Sync LTYPE2 This is an Ethertype value to match for tx and rx time sync packets.
15-0	TS_LTYPE1	R/W-0	0	Time Sync LTYPE1 This is an ethertype value to match for tx and rx time sync packets.

### 14.5.8.13 DLR\_LTYPE Register (offset = 30h) [reset = 80E1h]

DLR\_LTYPE is shown in [Figure 14-196](#) and described in [Table 14-213](#).

#### DLR LTYPE REGISTER

**Figure 14-196. DLR\_LTYPE Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-213. DLR\_LTYPE Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-0	DLR_LTYPE	R/W-0	0	DLR LTYPE

### 14.5.9 CPSW\_WR Registers

[Table 14-214](#) lists the memory-mapped registers for the CPSW\_WR. All register offset addresses not listed in [Table 14-214](#) should be considered as reserved locations and the register contents should not be modified.

**Table 14-214. CPSW\_WR REGISTERS**

Offset	Acronym	Register Name	Section
0h	IDVER		<a href="#">Section 14.5.9.1</a>
4h	SOFT_RESET		<a href="#">Section 14.5.9.2</a>
8h	CONTROL		<a href="#">Section 14.5.9.3</a>
Ch	INT_CONTROL		<a href="#">Section 14.5.9.4</a>
10h	C0_RX_THRESH_EN		<a href="#">Section 14.5.9.5</a>
14h	C0_RX_EN		<a href="#">Section 14.5.9.6</a>
18h	C0_TX_EN		<a href="#">Section 14.5.9.7</a>
1Ch	C0_MISC_EN		<a href="#">Section 14.5.9.8</a>
20h	C1_RX_THRESH_EN		<a href="#">Section 14.5.9.9</a>
24h	C1_RX_EN		<a href="#">Section 14.5.9.10</a>
28h	C1_TX_EN		<a href="#">Section 14.5.9.11</a>
2Ch	C1_MISC_EN		<a href="#">Section 14.5.9.12</a>
30h	C2_RX_THRESH_EN		<a href="#">Section 14.5.9.13</a>
34h	C2_RX_EN		<a href="#">Section 14.5.9.14</a>
38h	C2_TX_EN		<a href="#">Section 14.5.9.15</a>
3Ch	C2_MISC_EN		<a href="#">Section 14.5.9.16</a>
40h	C0_RX_THRESH_STAT		<a href="#">Section 14.5.9.17</a>
44h	C0_RX_STAT		<a href="#">Section 14.5.9.18</a>
48h	C0_TX_STAT		<a href="#">Section 14.5.9.19</a>
4Ch	C0_MISC_STAT		<a href="#">Section 14.5.9.20</a>
50h	C1_RX_THRESH_STAT		<a href="#">Section 14.5.9.21</a>
54h	C1_RX_STAT		<a href="#">Section 14.5.9.22</a>
58h	C1_TX_STAT		<a href="#">Section 14.5.9.23</a>
5Ch	C1_MISC_STAT		<a href="#">Section 14.5.9.24</a>
60h	C2_RX_THRESH_STAT		<a href="#">Section 14.5.9.25</a>
64h	C2_RX_STAT		<a href="#">Section 14.5.9.26</a>
68h	C2_TX_STAT		<a href="#">Section 14.5.9.27</a>
6Ch	C2_MISC_STAT		<a href="#">Section 14.5.9.28</a>

**Table 14-214. CPSW\_WR REGISTERS (continued)**

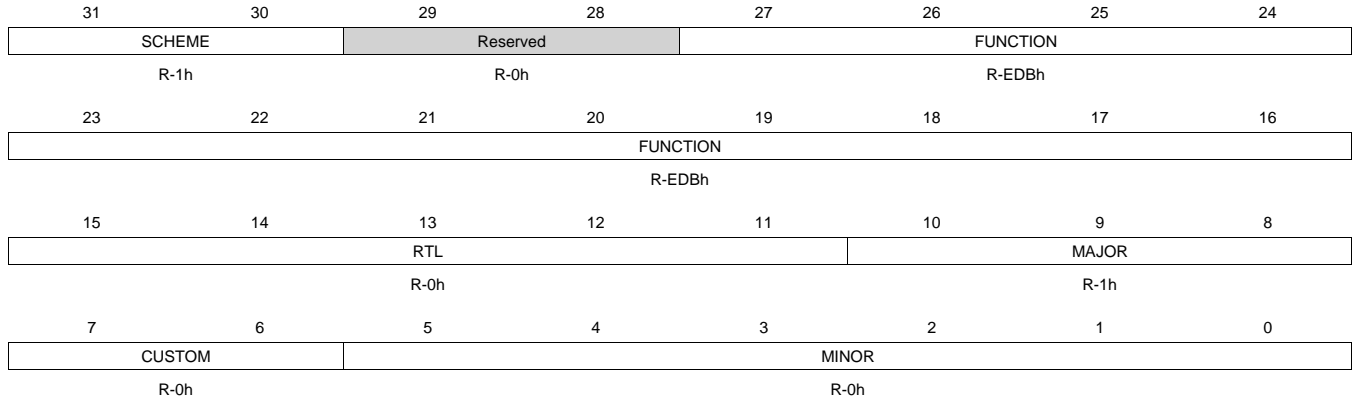

Offset	Acronym	Register Name	Section
70h	C0_RX_IMAX		<a href="#">Section 14.5.9.29</a>
74h	C0_TX_IMAX		<a href="#">Section 14.5.9.30</a>
78h	C1_RX_IMAX		<a href="#">Section 14.5.9.31</a>
7Ch	C1_TX_IMAX		<a href="#">Section 14.5.9.32</a>
80h	C2_RX_IMAX		<a href="#">Section 14.5.9.33</a>
84h	C2_TX_IMAX		<a href="#">Section 14.5.9.34</a>
88h	RGMII_CTL		<a href="#">Section 14.5.9.35</a>

### 14.5.9.1 IDVER Register (offset = 0h) [reset = 4EDB0100h]

IDVER is shown in [Figure 14-197](#) and described in [Table 14-215](#).

SUBSYSTEM ID VERSION REGISTER

**Figure 14-197. IDVER Register**

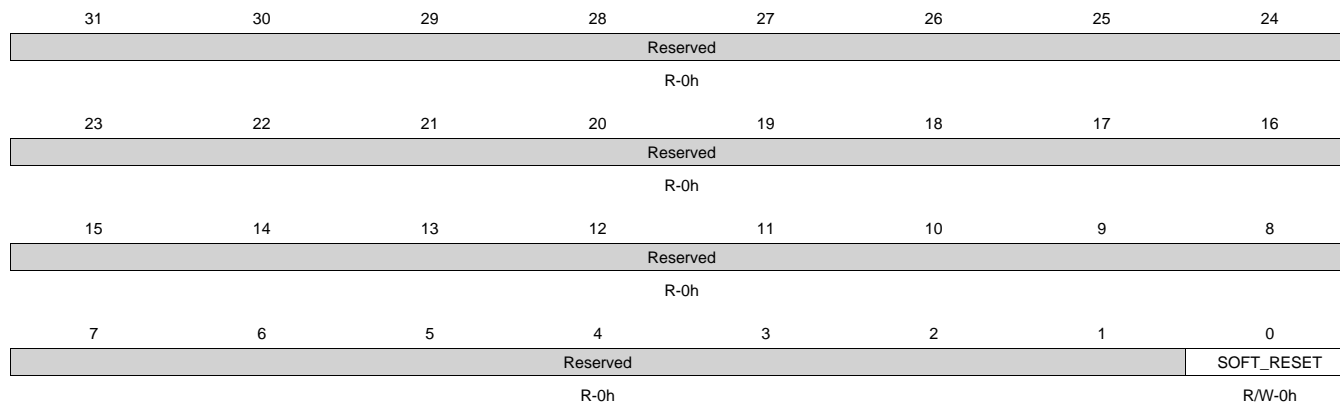

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-215. IDVER Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-30	SCHEME	R	1h	Scheme value
29-28	Reserved	R	0h	
27-16	FUNCTION	R	EDBh	function value
15-11	RTL	R	0h	rtl version
10-8	MAJOR	R	1h	major version
7-6	CUSTOM	R	0h	custom version
5-0	MINOR	R	0h	minor version

**14.5.9.2 SOFT\_RESET Register (offset = 4h) [reset = 0h]**

 SOFT\_RESET is shown in [Figure 14-198](#) and described in [Table 14-216](#).

**SUBSYSTEM SOFT RESET REGISTER**
**Figure 14-198. SOFT\_RESET Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-216. SOFT\_RESET Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	Reserved	R	0h	
0	SOFT_RESET	R/W	0h	Software reset - Writing a one to this bit causes the CPGMACSS_R logic to be reset (INT, REGS, CPPI). Software reset occurs on the clock following the register bit write.

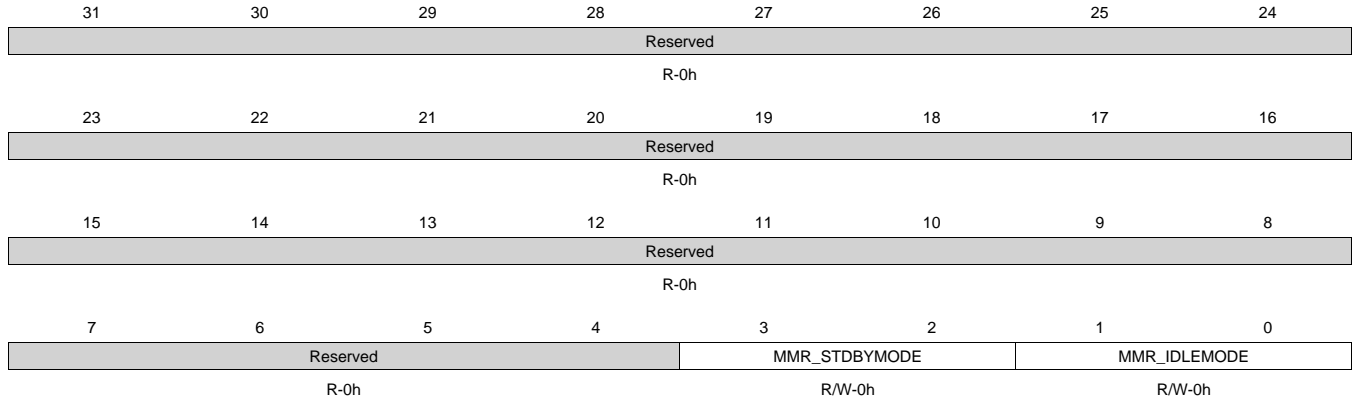

### 14.5.9.3 CONTROL Register (offset = 8h) [reset = 0h]

CONTROL is shown in [Figure 14-199](#) and described in [Table 14-217](#).

#### SUBSYSTEM CONTROL REGISTER

**Figure 14-199. CONTROL Register**

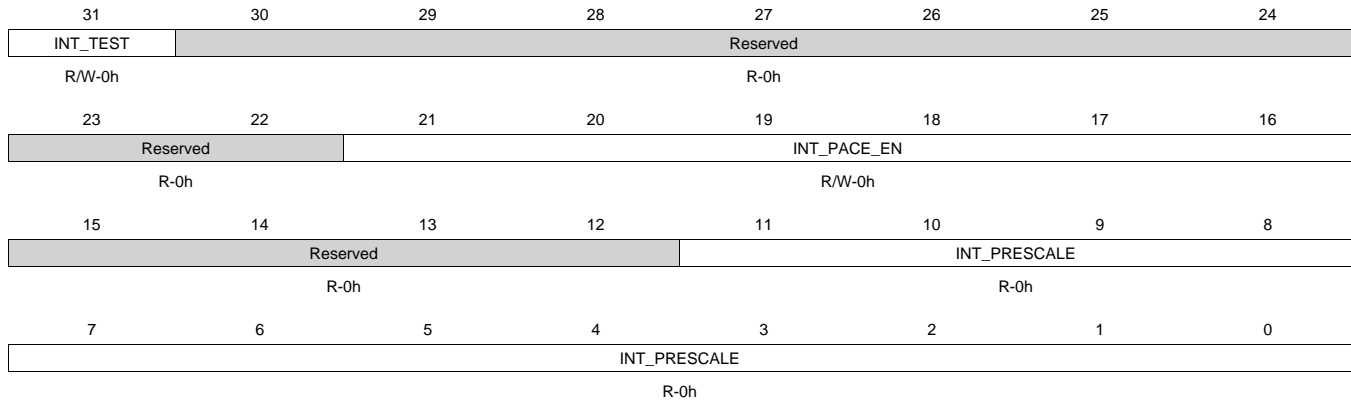

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-217. CONTROL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-4	Reserved	R	0h	
3-2	MMR_STDBYMODE	R/W	0h	Configuration of the local initiator state management mode. By definition, initiator may generate read/write transaction as long as it is out of STANDBY state. 0x0 = Force-standby mode : Local initiator is unconditionally placed in standbystate. 0x1 = No-standby mode : Local initiator is unconditionally placed out of standby state. 0x2 = Reserved : Reserved. 0x3 = Reserved : Reserved.
1-0	MMR_IDLEMODE	R/W	0h	Configuration of the local initiator state management mode. By definition, initiator may generate read/write transaction as long as it is out of IDLE state. 0x0 = Force-idle mode : Local initiator is unconditionally placed in idle state. 0x1 = No-idle mode : Local initiator is unconditionally placed out of idle state. 0x2 = Reserved : Reserved. 0x3 = Reserved : Reserved.

**14.5.9.4 INT\_CONTROL Register (offset = Ch) [reset = 0h]**

 INT\_CONTROL is shown in [Figure 14-200](#) and described in [Table 14-218](#).

**SUBSYSTEM INTERRUPT CONTROL**
**Figure 14-200. INT\_CONTROL Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-218. INT\_CONTROL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	INT_TEST	R/W	0h	Interrupt Test - Test bit to the interrupt pacing blocks
30-22	Reserved	R	0h	
21-16	INT_PACE_EN	R/W	0h	Interrupt Pacing Enable Bus int_pace_en[0] - Enables C0_Rx_Pulse Pacing (0 is pacing bypass) int_pace_en[1] - Enables C0_Tx_Pulse Pacing (0 is pacing bypass) int_pace_en[2] - Enables C1_Rx_Pulse Pacing (0 is pacing bypass) int_pace_en[3] - Enables C1_Tx_Pulse Pacing (0 is pacing bypass) int_pace_en[4] - Enables C2_Rx_Pulse Pacing (0 is pacing bypass) int_pace_en[5] - Enables C2_Tx_Pulse Pacing (0 is pacing bypass)
15-12	Reserved	R	0h	
11-0	INT_PRESCALE	R	0h	Interrupt Counter Prescaler - The number of MAIN_CLK periods in 4us.

**14.5.9.5 C0\_RX\_THRESH\_EN Register (offset = 10h) [reset = 0h]**

C0\_RX\_THRESH\_EN is shown in [Figure 14-201](#) and described in [Table 14-219](#).

SUBSYSTEM CORE 0 RECEIVE THRESHOLD INT ENABLE REGISTER

**Figure 14-201. C0\_RX\_THRESH\_EN Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

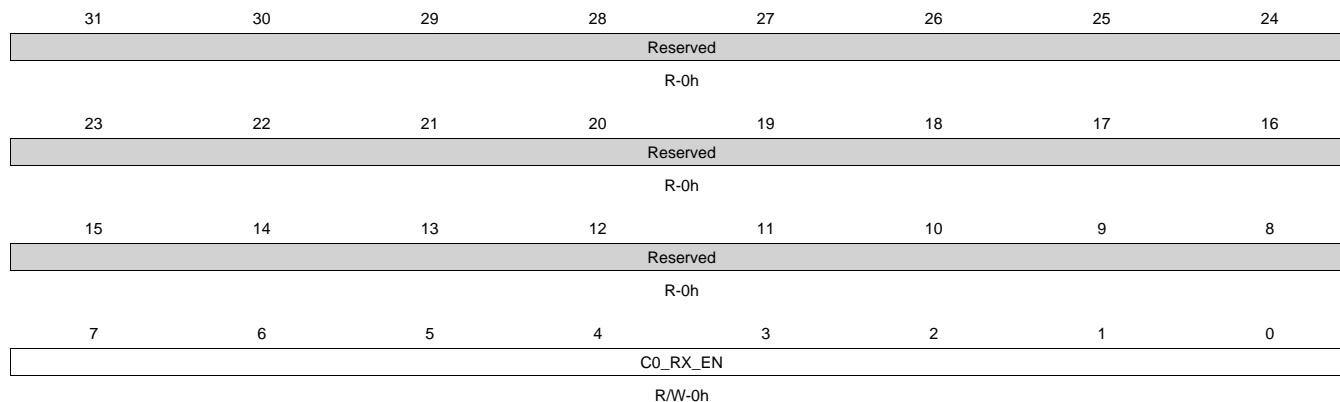

**Table 14-219. C0\_RX\_THRESH\_EN Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-8	Reserved	R	0h	
7-0	C0_RX_THRESH_EN	R/W	0h	Core 0 Receive Threshold Enable - Each bit in this register corresponds to the bit in the receive threshold interrupt that is enabled to generate an interrupt on C0_RX_THRESH_PULSE.

**14.5.9.6 C0\_RX\_EN Register (offset = 14h) [reset = 0h]**

 C0\_RX\_EN is shown in [Figure 14-202](#) and described in [Table 14-220](#).

SUBSYSTEM CORE 0 RECEIVE INTERRUPT ENABLE REGISTER

**Figure 14-202. C0\_RX\_EN Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-220. C0\_RX\_EN Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-8	Reserved	R	0h	
7-0	C0_RX_EN	R/W	0h	Core 0 Receive Enable - Each bit in this register corresponds to the bit in the rx interrupt that is enabled to generate an interrupt on C0_RX_PULSE.

**14.5.9.7 C0\_TX\_EN Register (offset = 18h) [reset = 0h]**

C0\_TX\_EN is shown in [Figure 14-203](#) and described in [Table 14-221](#).

**SUBSYSTEM CORE 0 TRANSMIT INTERRUPT ENABLE REGISTER**

**Figure 14-203. C0\_TX\_EN Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-221. C0\_TX\_EN Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-8	Reserved	R	0h	
7-0	C0_TX_EN	R/W	0h	Core 0 Transmit Enable - Each bit in this register corresponds to the bit in the tx interrupt that is enabled to generate an interrupt on C0_TX_PULSE.

**14.5.9.8 C0\_MISC\_EN Register (offset = 1Ch) [reset = 0h]**

 C0\_MISC\_EN is shown in [Figure 14-204](#) and described in [Table 14-222](#).

SUBSYSTEM CORE 0 MISC INTERRUPT ENABLE REGISTER

**Figure 14-204. C0\_MISC\_EN Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-222. C0\_MISC\_EN Register Field Descriptions**

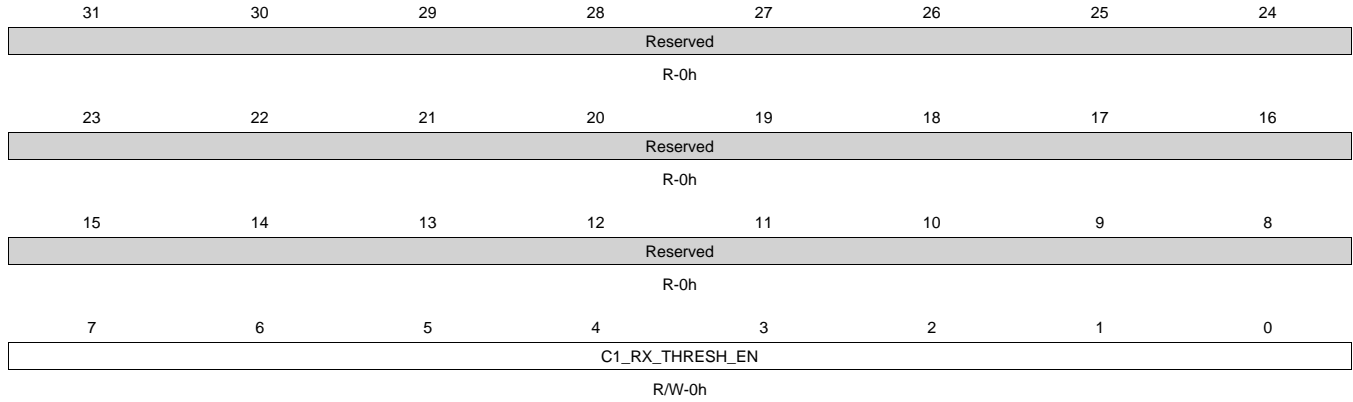

Bit	Field	Type	Reset	Description
31-5	Reserved	R	0h	
4-0	C0_MISC_EN	R/W	0h	Core 0 Misc Enable - Each bit in this register corresponds to the miscellaneous interrupt (evnt_pend, stat_pend, host_pend, mdio_linkint, mdio_userint) that is enabled to generate an interrupt on C0_Misc_PULSE. Bit 4 = evnt_pend Bit 3 = stat_pend Bit 2 = host_pend Bit 1 = mdio_linkint Bit 0 = mdio_userint

**14.5.9.9 C1\_RX\_THRESH\_EN Register (offset = 20h) [reset = 0h]**

C1\_RX\_THRESH\_EN is shown in [Figure 14-205](#) and described in [Table 14-223](#).

SUBSYSTEM CORE 1 RECEIVE THRESHOLD INT ENABLE REGISTER

**Figure 14-205. C1\_RX\_THRESH\_EN Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

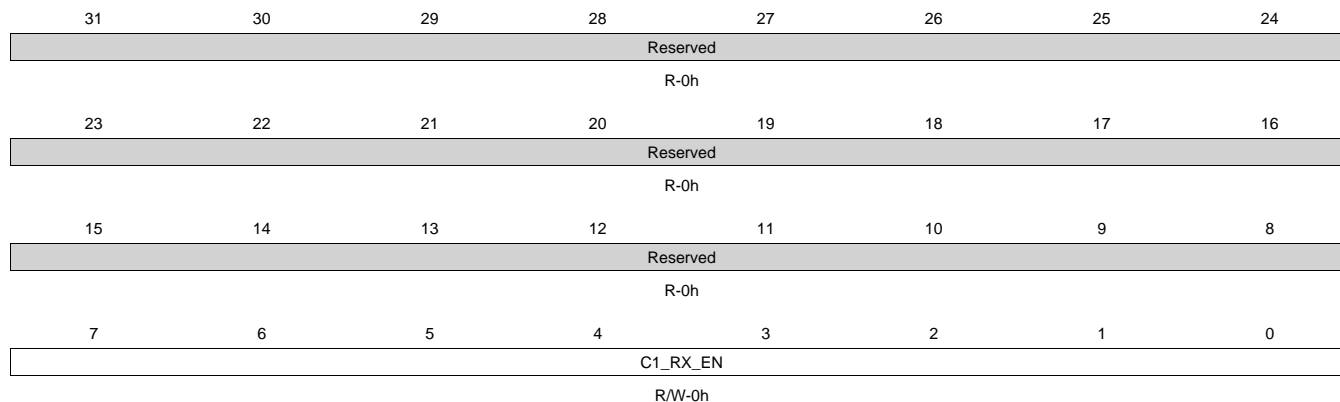

**Table 14-223. C1\_RX\_THRESH\_EN Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-8	Reserved	R	0h	
7-0	C1_RX_THRESH_EN	R/W	0h	Core 1 Receive Threshold Enable - Each bit in this register corresponds to the bit in the receive threshold interrupt that is enabled to generate an interrupt on C1_RX_THRESH_PULSE.

**14.5.9.10 C1\_RX\_EN Register (offset = 24h) [reset = 0h]**

 C1\_RX\_EN is shown in [Figure 14-206](#) and described in [Table 14-224](#).

SUBSYSTEM CORE 1 RECEIVE INTERRUPT ENABLE REGISTER

**Figure 14-206. C1\_RX\_EN Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-224. C1\_RX\_EN Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-8	Reserved	R	0h	
7-0	C1_RX_EN	R/W	0h	Core 1 Receive Enable - Each bit in this register corresponds to the bit in the rx interrupt that is enabled to generate an interrupt on C1_RX_PULSE.

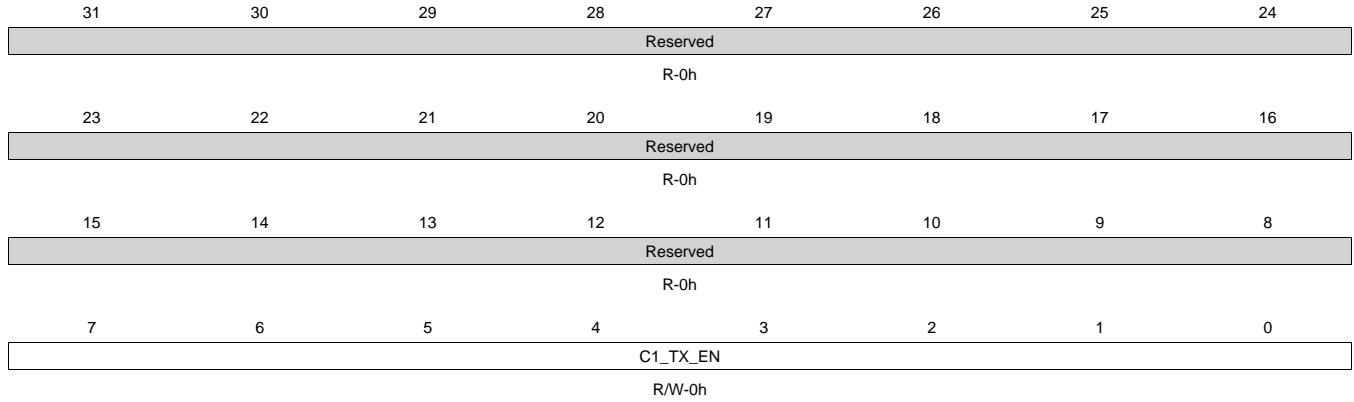

**14.5.9.11 C1\_TX\_EN Register (offset = 28h) [reset = 0h]**

C1\_TX\_EN is shown in [Figure 14-207](#) and described in [Table 14-225](#).

**SUBSYSTEM CORE 1 TRANSMIT INTERRUPT ENABLE REGISTER**

**Figure 14-207. C1\_TX\_EN Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

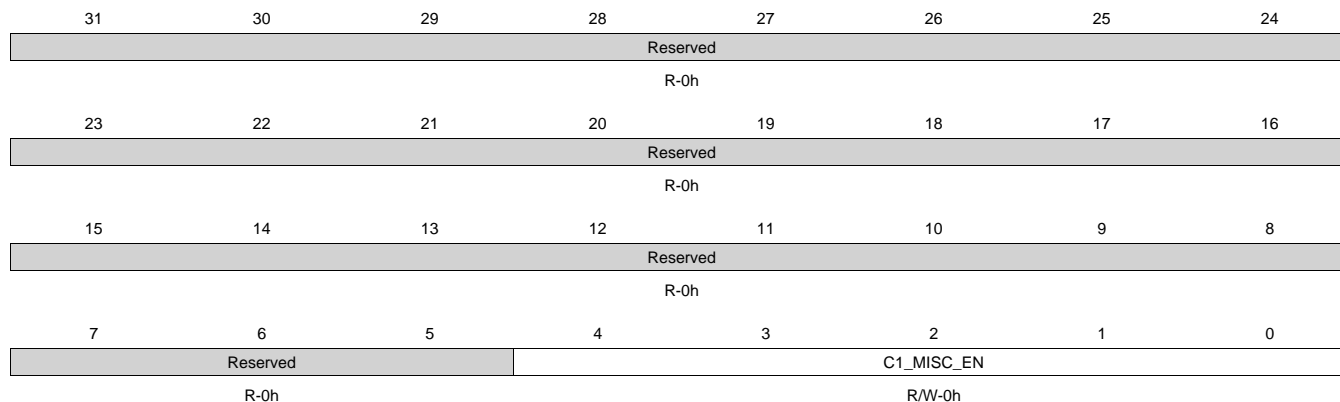

**Table 14-225. C1\_TX\_EN Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-8	Reserved	R	0h	
7-0	C1_TX_EN	R/W	0h	Core 1 Transmit Enable - Each bit in this register corresponds to the bit in the tx interrupt that is enabled to generate an interrupt on C1_TX_PULSE.

**14.5.9.12 C1\_MISC\_EN Register (offset = 2Ch) [reset = 0h]**

 C1\_MISC\_EN is shown in [Figure 14-208](#) and described in [Table 14-226](#).

SUBSYSTEM CORE 1 MISC INTERRUPT ENABLE REGISTER

**Figure 14-208. C1\_MISC\_EN Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-226. C1\_MISC\_EN Register Field Descriptions**

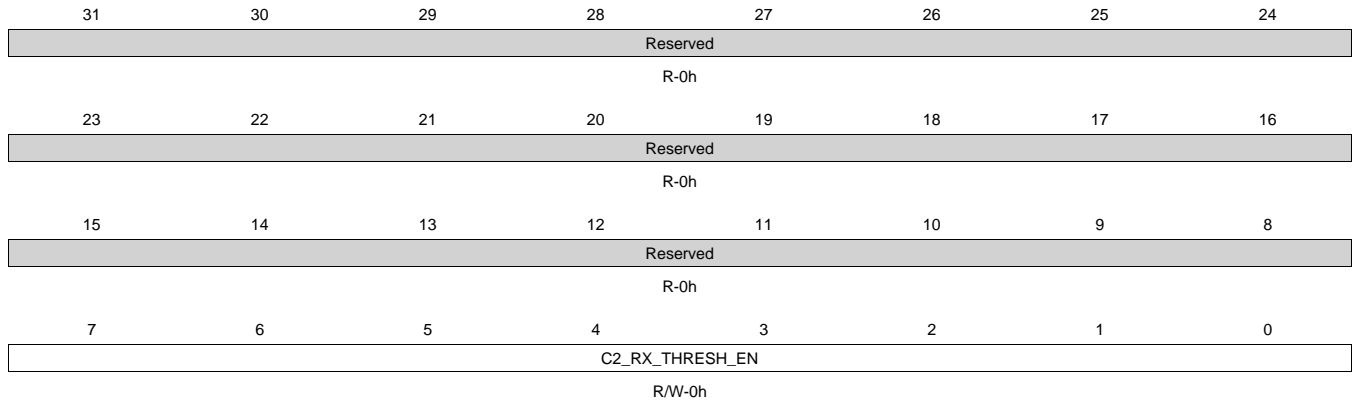

Bit	Field	Type	Reset	Description
31-5	Reserved	R	0h	
4-0	C1_MISC_EN	R/W	0h	Core 1 Misc Enable - Each bit in this register corresponds to the miscellaneous interrupt (evnt_pend, stat_pend, host_pend, mdio_linkint, mdio_userint) that is enabled to generate an interrupt on C1_Misc_PULSE. Bit 4 = evnt_pend Bit 3 = stat_pend Bit 2 = host_pend Bit 1 = mdio_linkint Bit 0 = mdio_userint

**14.5.9.13 C2\_RX\_THRESH\_EN Register (offset = 30h) [reset = 0h]**

C2\_RX\_THRESH\_EN is shown in [Figure 14-209](#) and described in [Table 14-227](#).

SUBSYSTEM CORE 2 RECEIVE THRESHOLD INT ENABLE REGISTER

**Figure 14-209. C2\_RX\_THRESH\_EN Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

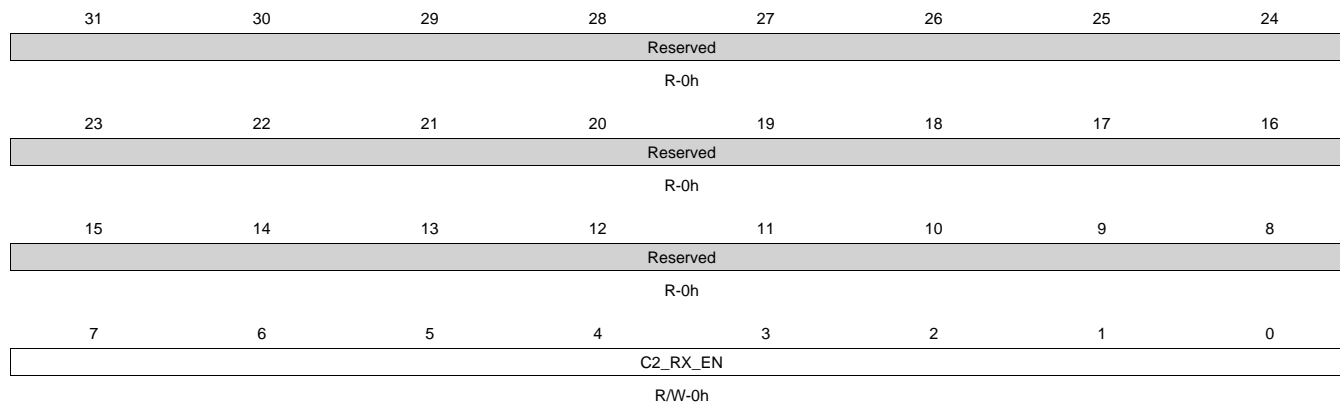

**Table 14-227. C2\_RX\_THRESH\_EN Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-8	Reserved	R	0h	
7-0	C2_RX_THRESH_EN	R/W	0h	Core 2 Receive Threshold Enable - Each bit in this register corresponds to the bit in the receive threshold interrupt that is enabled to generate an interrupt on C2_RX_THRESH_PULSE.

**14.5.9.14 C2\_RX\_EN Register (offset = 34h) [reset = 0h]**

 C2\_RX\_EN is shown in [Figure 14-210](#) and described in [Table 14-228](#).

SUBSYSTEM CORE 2 RECEIVE INTERRUPT ENABLE REGISTER

**Figure 14-210. C2\_RX\_EN Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-228. C2\_RX\_EN Register Field Descriptions**

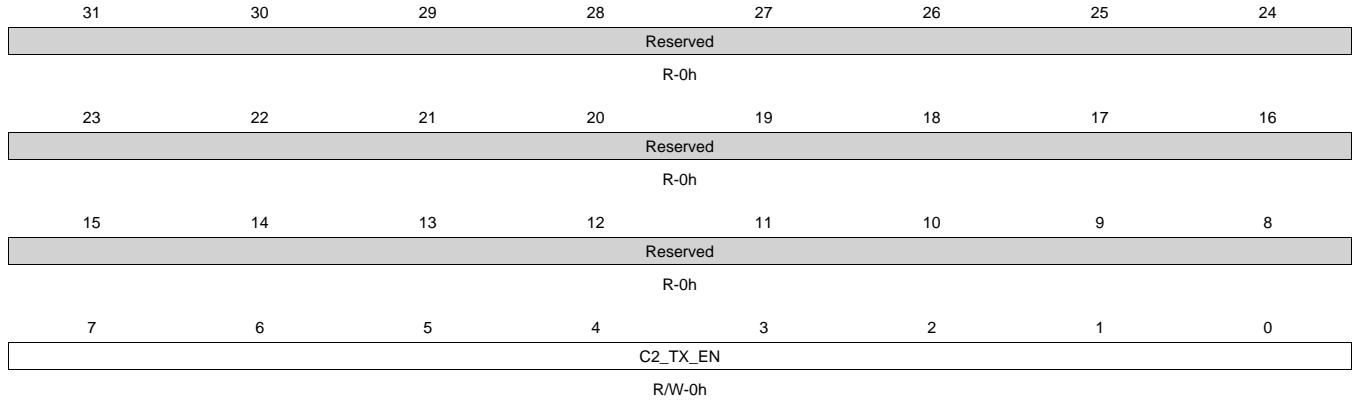

Bit	Field	Type	Reset	Description
31-8	Reserved	R	0h	
7-0	C2_RX_EN	R/W	0h	Core 2 Receive Enable - Each bit in this register corresponds to the bit in the rx interrupt that is enabled to generate an interrupt on C2_RX_PULSE.

**14.5.9.15 C2\_TX\_EN Register (offset = 38h) [reset = 0h]**

C2\_TX\_EN is shown in [Figure 14-211](#) and described in [Table 14-229](#).

**SUBSYSTEM CORE 2 TRANSMIT INTERRUPT ENABLE REGISTER**

**Figure 14-211. C2\_TX\_EN Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

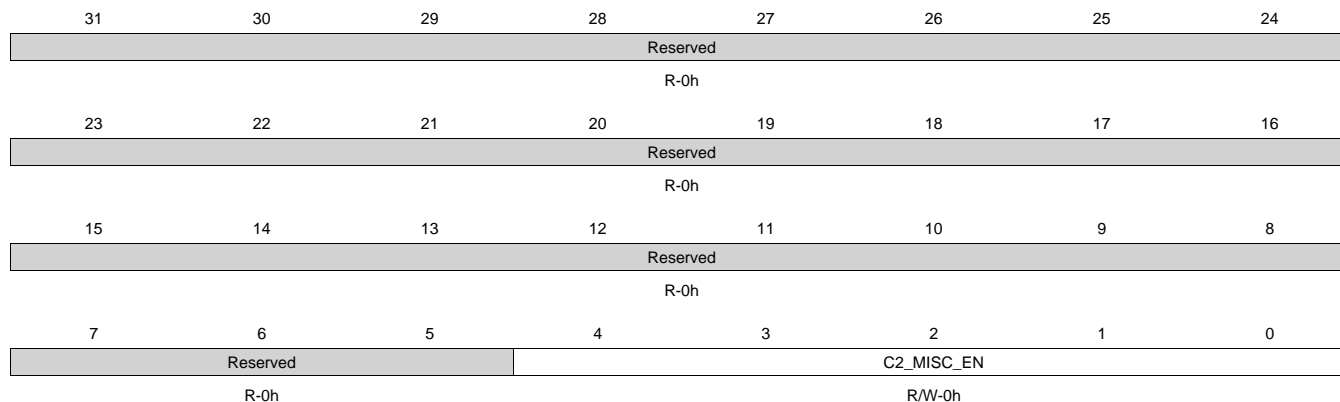

**Table 14-229. C2\_TX\_EN Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-8	Reserved	R	0h	
7-0	C2_TX_EN	R/W	0h	Core 2 Transmit Enable - Each bit in this register corresponds to the bit in the tx interrupt that is enabled to generate an interrupt on C2_TX_PULSE.

**14.5.9.16 C2\_MISC\_EN Register (offset = 3Ch) [reset = 0h]**

 C2\_MISC\_EN is shown in [Figure 14-212](#) and described in [Table 14-230](#).

SUBSYSTEM CORE 2 MISC INTERRUPT ENABLE REGISTER

**Figure 14-212. C2\_MISC\_EN Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

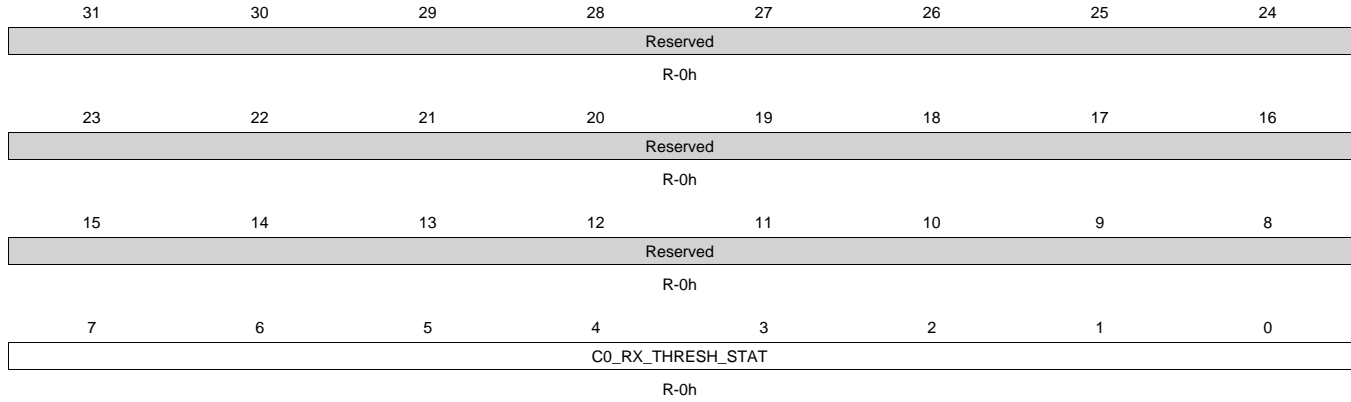

**Table 14-230. C2\_MISC\_EN Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-5	Reserved	R	0h	
4-0	C2_MISC_EN	R/W	0h	Core 2 Misc Enable - Each bit in this register corresponds to the miscellaneous interrupt (evnt_pend, stat_pend, host_pend, mdio_linkint, mdio_userint) that is enabled to generate an interrupt on C2_Misc_PULSE. Bit 4 = evnt_pend Bit 3 = stat_pend Bit 2 = host_pend Bit 1 = mdio_linkint Bit 0 = mdio_userint

**14.5.9.17 C0\_RX\_THRESH\_STAT Register (offset = 40h) [reset = 0h]**

 C0\_RX\_THRESH\_STAT is shown in [Figure 14-213](#) and described in [Table 14-231](#).

SUBSYSTEM CORE 0 RX THRESHOLD MASKED INT STATUS REGISTER

**Figure 14-213. C0\_RX\_THRESH\_STAT Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

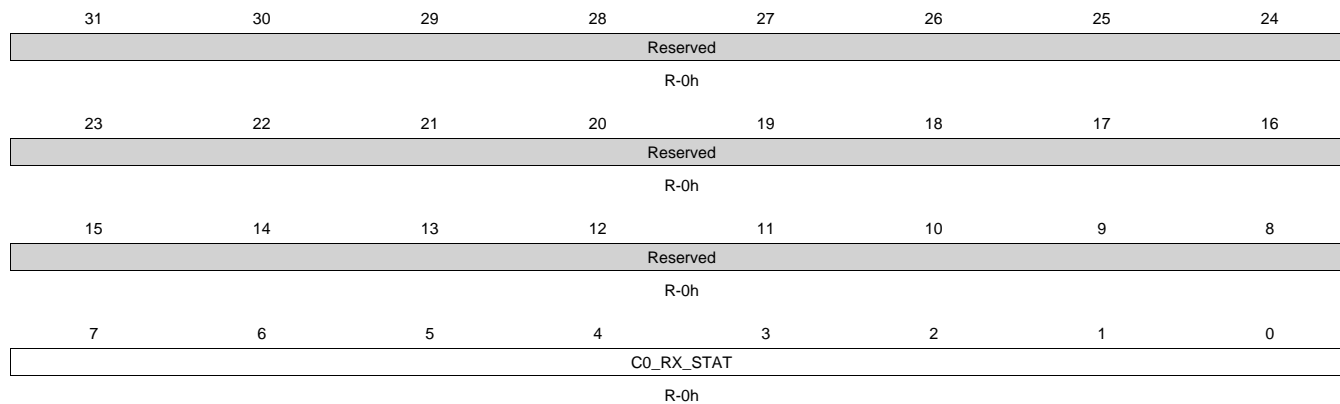

**Table 14-231. C0\_RX\_THRESH\_STAT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-8	Reserved	R	0h	
7-0	C0_RX_THRESH_STAT	R	0h	Core 0 Receive Threshold Masked Interrupt Status - Each bit in this read only register corresponds to the bit in the receive threshold interrupt that is enabled and generating an interrupt on C0_RX_THRESH_PULSE.

**14.5.9.18 C0\_RX\_STAT Register (offset = 44h) [reset = 0h]**

 C0\_RX\_STAT is shown in [Figure 14-214](#) and described in [Table 14-232](#).

SUBSYSTEM CORE 0 RX INTERRUPT MASKED INT STATUS REGISTER

**Figure 14-214. C0\_RX\_STAT Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-232. C0\_RX\_STAT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-8	Reserved	R	0h	
7-0	C0_RX_STAT	R	0h	Core 0 Receive Masked Interrupt Status - Each bit in this read only register corresponds to the bit in the Rx interrupt that is enabled and generating an interrupt on C0_RX_PULSE.

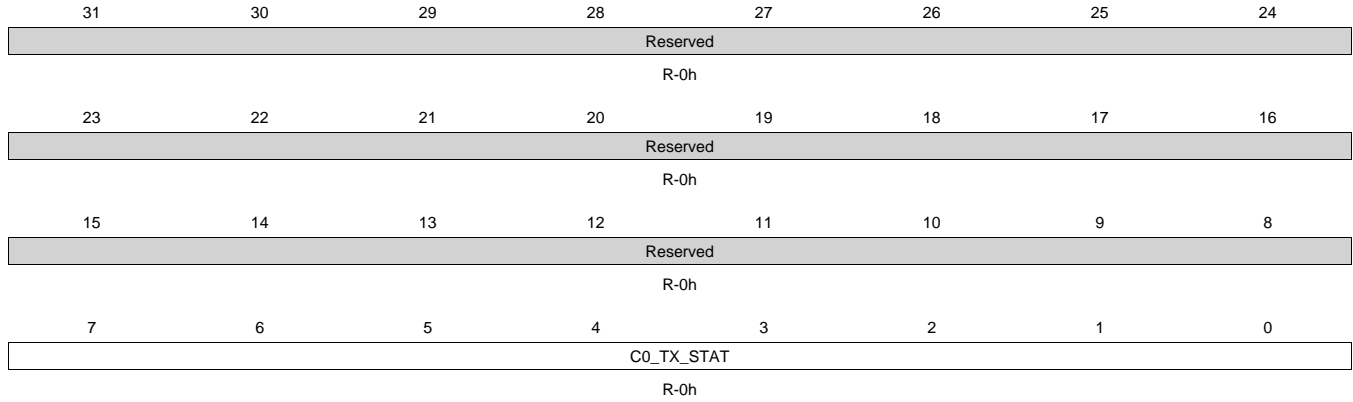

**14.5.9.19 C0\_TX\_STAT Register (offset = 48h) [reset = 0h]**

C0\_TX\_STAT is shown in [Figure 14-215](#) and described in [Table 14-233](#).

SUBSYSTEM CORE 0 TX INTERRUPT MASKED INT STATUS REGISTER

**Figure 14-215. C0\_TX\_STAT Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

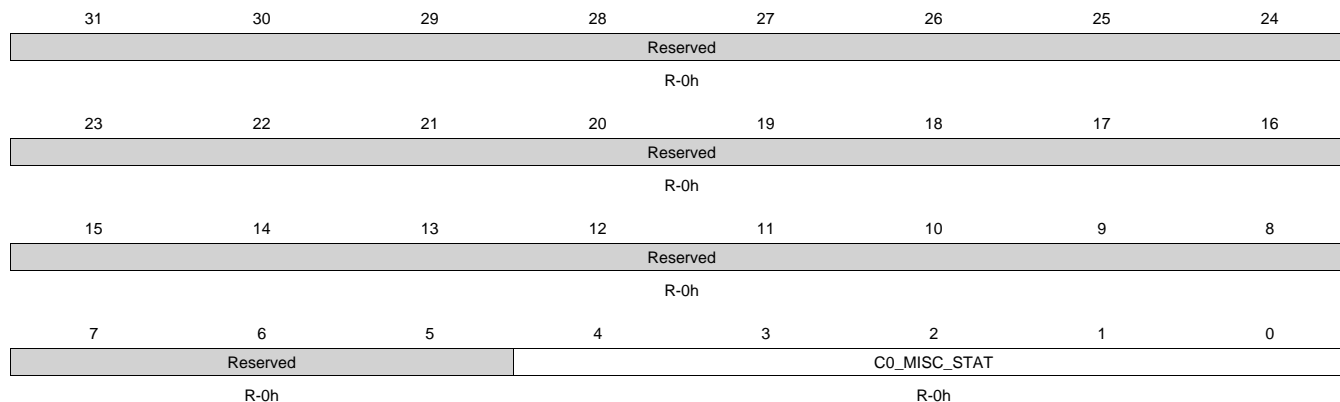

**Table 14-233. C0\_TX\_STAT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-8	Reserved	R	0h	
7-0	C0_TX_STAT	R	0h	Core 0 Transmit Masked Interrupt Status - Each bit in this read only register corresponds to the bit in the Tx interrupt that is enabled and generating an interrupt on C0_TX_PULSE .

**14.5.9.20 C0\_MISC\_STAT Register (offset = 4Ch) [reset = 0h]**

 C0\_MISC\_STAT is shown in [Figure 14-216](#) and described in [Table 14-234](#).

SUBSYSTEM CORE 0 MISC INTERRUPT MASKED INT STATUS REGISTER

**Figure 14-216. C0\_MISC\_STAT Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 14-234. C0\_MISC\_STAT Register Field Descriptions**

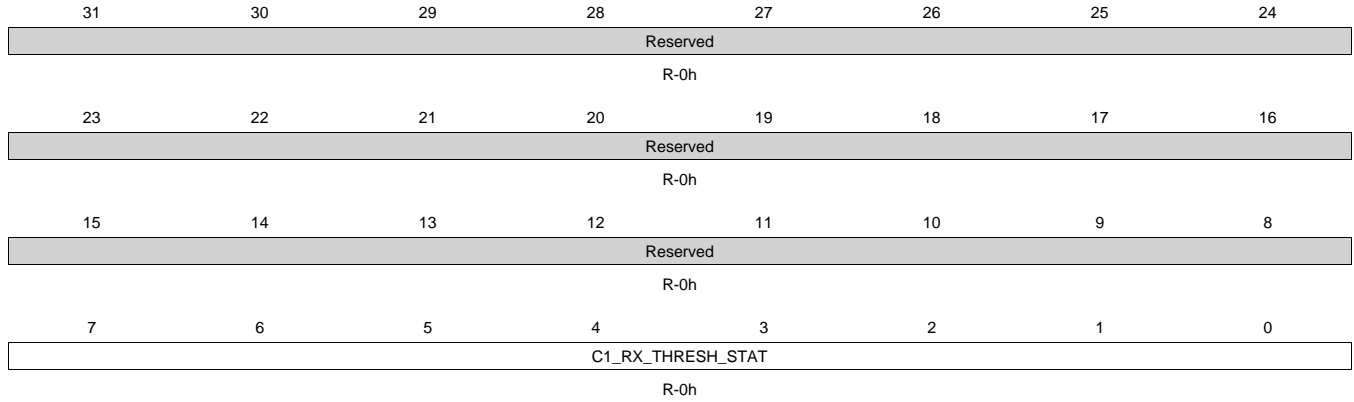

Bit	Field	Type	Reset	Description
31-5	Reserved	R	0h	
4-0	C0_MISC_STAT	R	0h	Core 0 Misc Masked Interrupt Status - Each bit in this register corresponds to the miscellaneous interrupt (evnt_pend, stat_pend, host_pend, mdio_linkint, mdio_userint) that is enabled and generating an interrupt on C0_MISC_PULSE. Bit 4 = evnt_pend Bit 3 = stat_pend Bit 2 = host_pend Bit 1 = mdio_linkint Bit 0 = mdio_userint

**14.5.9.21 C1\_RX\_THRESH\_STAT Register (offset = 50h) [reset = 0h]**

C1\_RX\_THRESH\_STAT is shown in [Figure 14-217](#) and described in [Table 14-235](#).

SUBSYSTEM CORE 1 RX THRESHOLD MASKED INT STATUS REGISTER

**Figure 14-217. C1\_RX\_THRESH\_STAT Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

2-1	RGMII1_SPEED	R	0h	RGMII1 Speed - This is the CPRGMII speed output signal 00 - 10Mbps mode 01 - 100Mbps mode 10 - 1000Mbps (gig) mode 11 - reserved
0	RGMII1_LINK	R	0h	RGMII1 Link Indicator - This is the CPRGMII link output signal 0 - RGMII1 link is down

**14.5.10 Management Data Input/Output (MDIO) Registers**

This section describes the memory-mapped registers for the Management Data Input/Output (MDIO).

[Table 14-250](#) lists the memory-mapped registers for the Management Data Input/Output (MDIO). See the device-specific data manual for the memory address of these registers.

**Table 14-250. Management Data Input/Output (MDIO) Registers**

Offset	Acronym	Register Description	Section
0	MDIOVER	MDIO Version Register	<a href="#">Section 14.5.10.1</a>
4h	MDIOCONTROL	MDIO Control Register	<a href="#">Section 14.5.10.2</a>
8h	MDIOALIVE	PHY Alive Status Register	<a href="#">Section 14.5.10.3</a>
Ch	MDIOLINK	PHY Link Status Register	<a href="#">Section 14.5.10.4</a>
10h	MDIOLINKINTRAW	MDIO Link Status Change Interrupt Register	<a href="#">Section 14.5.10.5</a>
14h	MDIOLINKINTMASKED	MDIO Link Status Change Interrupt Register (Masked Value)	<a href="#">Section 14.5.10.6</a>
20h	MDIOUSERINTRAW	MDIO User Command Complete Interrupt Register (Raw Value)	<a href="#">Section 14.5.10.7</a>
24h	MDIOUSERINTMASKED	MDIO User Command Complete Interrupt Register (Masked Value)	<a href="#">Section 14.5.10.8</a>
28h	MDIOUSERINTMASKSET	MDIO User Command Complete Interrupt Mask Set Register	<a href="#">Section 14.5.10.9</a>
2Ch	MDIOUSERINTMASKCLR	MDIO User Interrupt Mask Clear Register	<a href="#">Section 14.5.10.10</a>
80h	MDIOUSERACCESS0	MDIO User Access Register 0	<a href="#">Section 14.5.10.11</a>
84h	MDIOUSERPHYSEL0	MDIO User PHY Select Register 0	<a href="#">Section 14.5.10.12</a>
88h	MDIOUSERACCESS1	MDIO User Access Register 1	<a href="#">Section 14.5.10.13</a>
8Ch	MDIOUSERPHYSEL1	MDIO User PHY Select Register 1	<a href="#">Section 14.5.10.14</a>

#### 14.5.10.1 MDIO Version Register (MDIOVER)

The MDIO version register (MDIOVER) is shown in [Figure 14-232](#) and described in [Table 14-251](#).

**Figure 14-232. MDIO Version Register (MDIOVER)**

LEGEND: R = Read only; -n = value after reset

**Table 14-251. MDIO Version Register (MDIOVER) Field Descriptions**

Bit	Field	Value	Description
31-16	MODID	0-FFFh	Identifies type of peripheral.
15-8	REVMAJ	0-FFh	Management interface module major revision value.
7-0	REVMIN	0-FFh	Management interface module minor revision value.

### 14.5.10.2 MDIO Control Register (MDIOCONTROL)

The MDIO control register (MDIOCONTROL) is shown in [Figure 14-233](#) and described in [Table 14-252](#).

**Figure 14-233. MDIO Control Register (MDIOCONTROL)**

31	30	29	28	24	23	21	20	19	18	17	16
IDLE	ENABLE	Reserved	HIGHEST_USER_CHANNEL	Reserved	PREAMBLE	FAULT	FAULTENB	INTTESTENB	Reserved		
R-0x1	R/W-0x0	R-0x0	R-0x1		R-0x0		R/W-0x0	RWC-0x0	R/W-0x0	R/W-0x0	R-0x0
15											
CLKDIV											
R/W-0x255											
0											

LEGEND: R/W = Read/Write; RWC = Read/Write/Clear; R = Read only; -n = value after reset

**Table 14-252. MDIO Control Register (MDIOCONTROL) Field Descriptions**

Bit	Field	Value	Description
31	IDLE	0 1	MDIO state machine IDLE. Set to 1 when the state machine is in the idle state. State machine is not in idle state. State machine is in idle state.
30	ENABLE	0 1	Enable control. If the MDIO state machine is active at the time it is disabled, it will complete the current operation before halting and setting the idle bit. If using byte access, the enable bit has to be the last bit written in this register. Disables the MDIO state machine. Enable the MDIO state machine.
29	Reserved	0	Reserved.
28-24	HIGHEST_USER_CHANNEL	0-1Fh	Highest user channel. This field specifies the highest user access channel that is available in the module and is currently set to 1. This implies that the MDIOUSERACCESS1 register is the highest available user access channel.
23-21	Reserved	0	Reserved.
20	PREAMBLE	0 1	Preamble disable. Standard MDIO preamble is used. Disables this device from sending MDIO frame preambles.
19	FAULT	0 1	Fault indicator. This bit is set to 1 if the MDIO pins fail to read back what the device is driving onto them. This indicates a physical layer fault and the module state machine is reset. Writing a 1 to it clears this bit. No failure. Physical layer fault; the MDIO state machine is reset.
18	FAULTENB	0 1	Fault detect enable. This bit has to be set to 1 to enable the physical layer fault detection. Disables the physical layer fault detection. Enables the physical layer fault detection.
17	INTTESTENB	0 1	Interrupt test enable. This bit can be set to 1 to enable the host to set the USERINT and LINKINT bits for test purposes. Interrupt bits are not set. Enables the host to set the USERINT and LINKINT bits for test purposes.
16	Reserved	0	Reserved.
15-0	CLKDIV	0-FFFFh	Clock divider. This field specifies the division ratio between CLK and the frequency of MDCLK. MDCLK is disabled when clkdiv is set to 0. MDCLK frequency = clk frequency/(clkdiv+1).

### 14.5.10.3 PHY Acknowledge Status Register (MDIOALIVE)

The PHY acknowledge status register (MDIOALIVE) is shown in [Figure 14-234](#) and described in [Table 14-253](#).

**Figure 14-234. PHY Acknowledge Status Register (MDIOALIVE)**

31	ALIVE	0
RWC-0x0		

LEGEND: RWC = Read/Write/Clear

**Table 14-253. PHY Acknowledge Status Register (MDIOALIVE) Field Descriptions**

Bit	Field	Value	Description
31-0	ALIVE	0-FFFF FFFFh	MDIO alive. Each of the 32 bits of this register is set if the most recent access to the PHY with address corresponding to the register bit number was acknowledged by the PHY, the bit is reset if the PHY fails to acknowledge the access. Both the user and polling accesses to a PHY will cause the corresponding alive bit to be updated. The alive bits are only meant to be used to give an indication of the presence or not of a PHY with the corresponding address. Writing a 1 to any bit will clear it, writing a 0 has no effect.

#### 14.5.10.4 PHY Link Status Register (MDIOLINK)

The PHY link status register (MDIOLINK) is shown in [Figure 14-235](#) and described in [Table 14-254](#).

**Figure 14-235. PHY Link Status Register (MDIOLINK)**

31	LINK	0
R-0x0		

LEGEND: R = Read only; -n = value after reset

**Table 14-254. PHY Link Status Register (MDIOLINK) Field Descriptions**

Bit	Field	Value	Description
31-0	LINK	0-FFFF FFFFh	MDIO link state. This register is updated after a read of the Generic Status Register of a PHY. The bit is set if the PHY with the corresponding address has link and the PHY acknowledges the read transaction. The bit is reset if the PHY indicates it does not have link or fails to acknowledge the read transaction. Writes to the register have no effect. In addition, the status of the two PHYs specified in the MDIOUSERPHYSEL <sub>n</sub> registers can be determined using the MLINK input pins. This is determined by the LINKSEL bit in the MDIOUSERPHYSEL <sub>n</sub> register.

**14.5.10.5 MDIO Link Status Change Interrupt Register (MDIOLINKINTRAW)**

The MDIO link status change interrupt register (MDIOLINKINTRAW) is shown in [Figure 14-236](#) and described in [Table 14-255](#).

**Figure 14-236. MDIO Link Status Change Interrupt Register (MDIOLINKINTRAW)**

LEGEND: RWC = Read/Write/Clear; R = Read only; -n = value after reset

**Table 14-255. MDIO Link Status Change Interrupt Register (MDIOLINKINTRAW) Field Descriptions**

Bit	Field	Value	Description
31-2	Reserved	0	Reserved.
1-0	LINKINTRAW	0-3h	MDIO link change event, raw value. When asserted 1, a bit indicates that there was an MDIO link change event (i.e. change in the MDIOLINK register) corresponding to the PHY address in the MDIOUSERPHYSEL <sub>n</sub> register. LINKINTRAW[0] and LINKINTRAW[1] correspond to MDIOUSERPHYSEL0 and MDIOUSERPHYSEL1, respectively. Writing a 1 will clear the event and writing 0 has no effect. If the INTTESTENB bit in the MDIOCONTROL register is set, the host may set the LINKINTRAW bits to a 1. This mode may be used for test purposes.

**14.5.10.6 MDIO Link Status Change Interrupt Register (Masked Value) (MDIOLINKINTMASKED)**

The MDIO link status change interrupt register (Masked Value) (MDIOLINKINTMASKED) is shown in [Figure 14-237](#) and described in [Table 14-256](#).

**Figure 14-237. MDIO Link Status Change Interrupt Register (Masked Value) (MDIOLINKINTMASKED)**

LEGEND: RWC = Read/Write/Clear; R = Read only; -n = value after reset

**Table 14-256. MDIO Link Status Change Interrupt Register (Masked Value) (MDIOLINKINTMASKED) Field Descriptions**

Bit	Field	Value	Description
31-2	Reserved	0	Reserved.
1-0	LINKINTMASKED	0-3h	MDIO link change interrupt, masked value. When asserted 1, a bit indicates that there was an MDIO link change event (i.e. change in the MDIO Link register) corresponding to the PHY address in the MDIOUSERPHYSEL <sub>n</sub> register and the corresponding LINKINTENB bit was set. LINKINTMASKED[0] and LINKINTMASKED[1] correspond to MDIOUSERPHYSEL0 and MDIOUSERPHYSEL1, respectively. Writing a 1 will clear the interrupt and writing 0 has no effect. If the INTTESTENB bit in the MDIOCONTROL register is set, the host may set the LINKINT bits to a 1. This mode may be used for test purposes.

### 14.5.10.7 MDIO User Command Complete Interrupt Register (Raw Value) (MDIOUSERINTRAW)

The MDIO user command complete interrupt register (Raw Value) (MDIOUSERINTRAW) is shown in [Figure 14-238](#) and described in [Table 14-257](#).

**Figure 14-238. MDIO User Command Complete Interrupt Register (Raw Value) (MDIOUSERINTRAW)**

31	Reserved				16
R-0x0					
15	Reserved		2	1	0
R-0x0				USERINTRAW	
				RWC-0x0	

LEGEND: RWC = Read/Write/Clear; R = Read only; -n = value after reset

**Table 14-257. MDIO User Command Complete Interrupt Register (Raw Value) (MDIOUSERINTRAW) Field Descriptions**

Bit	Field	Value	Description
31-2	Reserved	0	Reserved.
1-0	USERINTRAW	0-3h	Raw value of MDIO user command complete event for the MDIOUSERACCESS1 register through the MDIOUSERACCESS0 register, respectively. When asserted 1, a bit indicates that the previously scheduled PHY read or write command using that particular MDIOUSERACCESSn register has completed. Writing a 1 will clear the event and writing 0 has no effect. If the INTTESTENB bit in the MDIOCONTROL register is set, the host may set the USERINTRAW bits to a 1. This mode may be used for test purposes.

### 14.5.10.8 MDIO User Command Complete Interrupt Register (Masked Value) (MDIOUSERINTMASKED)

The MDIO user command complete interrupt register (Masked Value) (MDIOUSERINTMASKED) is shown in [Figure 14-239](#) and described in [Table 14-258](#).

**Figure 14-239. MDIO User Command Complete Interrupt Register (Masked Value) (MDIOUSERINTMASKED)**

31	Reserved				16
R-0x0					
15	Reserved		2	1	0
R-0x0				USERINTMASKED	
				RWC-0x0	

LEGEND: RWC = Read/Write/Clear; R = Read only; -n = value after reset

**Table 14-258. MDIO User Command Complete Interrupt Register (Masked Value) (MDIOUSERINTMASKED) Field Descriptions**

Bit	Field	Value	Description
31-2	Reserved	0	Reserved.
1-0	USERINTMASKED	0-3h	Masked value of MDIO user command complete interrupt for the MDIOUSERACCESS1 register through the MDIOUSERACCESS0 register, respectively. When asserted 1, a bit indicates that the previously scheduled PHY read or write command using that particular MDIOUSERACCESSn register has completed and the corresponding USERINTMASKSET bit is set to 1. Writing a 1 will clear the interrupt and writing 0 has no effect. If the INTTESTENB bit in the MDIOCONTROL register is set, the host may set the USERINTMASKED bits to a 1. This mode may be used for test purposes.

### 14.5.10.9 MDIO User Command Complete Interrupt Mask Set Register (MDIOUSERINTMASKSET)

The MDIO user command complete interrupt mask set register (MDIOUSERINTMASKSET) is shown in [Figure 14-240](#) and described in [Table 14-259](#).

**Figure 14-240. MDIO User Command Complete Interrupt Mask Set Register (MDIOUSERINTMASKSET)**

LEGEND: RWC = Read/Write/Clear; R = Read only; -n = value after reset

**Table 14-259. MDIO User Command Complete Interrupt Mask Set Register (MDIOUSERINTMASKSET) Field Descriptions**

Bit	Field	Value	Description
31-2	Reserved	0	Reserved.
1-0	USERINTMASKSET	0-3h	MDIO user interrupt mask set for USERINTMASKED, respectively. Writing a bit to 1 will enable MDIO user command complete interrupts for that particular MDIOUSERACCESS <sub>n</sub> register. MDIO user interrupt for a particular MDIOUSERACCESS <sub>n</sub> register is disabled if the corresponding bit is 0. Writing a 0 to this register has no effect.

### 14.5.10.10 MDIO User Command Complete Interrupt Mask Clear Register (MDIOUSERINTMASKCLR)

The MDIO user interrupt mask clear register (MDIOUSERINTMASKCLR) is shown in [Figure 14-241](#) and described in [Table 14-260](#).

**Figure 14-241. MDIO User Command Complete Interrupt Mask Clear Register (MDIOUSERINTMASKCLR)**

LEGEND: RWC = Read/Write/Clear; R = Read only; -n = value after reset

**Table 14-260. MDIO User Command Complete Interrupt Mask Clear Register (MDIOUSERINTMASKCLR) Field Descriptions**

Bit	Field	Value	Description
31-2	Reserved	0	Reserved.
1-0	USERINTMASKCLEAR	0-3h	MDIO user command complete interrupt mask clear for USERINTMASKED, respectively. Writing a bit to 1 will disable further user command complete interrupts for that particular MDIOUSERACCESSn register. Writing a 0 to this register has no effect.

### 14.5.10.11 MDIO User Access Register 0 (MDIOUSERACCESS0)

The MDIO user access register 0 (MDIOUSERACCESS0) is shown in [Figure 14-242](#) and described in [Table 14-261](#).

**Figure 14-242. MDIO User Access Register 0 (MDIOUSERACCESS0)**

LEGEND: R/W = Read/Write; R = Read only; S = Status; -n = value after reset

**Table 14-261. MDIO User Access Register 0 (MDIOUSERACCESS0) Field Descriptions**

Bit	Field	Value	Description
31	GO	0-1	Go. Writing a 1 to this bit causes the MDIO state machine to perform an MDIO access when it is convenient for it to do so, this is not an instantaneous process. Writing a 0 to this bit has no effect. This bit is write able only if the MDIO state machine is enabled. This bit will self clear when the requested access has been completed. Any writes to the MDIOUSERACCESS0 register are blocked when the GO bit is 1. If byte access is being used, the GO bit should be written last.
30	WRITE	0-1	Write enable. Setting this bit to a 1 causes the MDIO transaction to be a register write, otherwise it is a register read.
29	ACK	0-1	Acknowledge. This bit is set if the PHY acknowledged the read transaction.
28-26	Reserved	0	Reserved.
25-21	REGADR	0-1Fh	Register address. Specifies the PHY register to be accessed for this transaction.
20-16	PHYADR	0-1Fh	PHY address. Specifies the PHY to be accesses for this transaction.
15-0	DATA	0-FFFFh	User data. The data value read from or to be written to the specified PHY register.

**14.5.10.12 MDIO User PHY Select Register 0 (MDIOUSERPHYSEL0)**

The MDIO user PHY select register 0 (MDIOUSERPHYSEL0) is shown in [Figure 14-243](#) and described in [Table 14-262](#).

**Figure 14-243. MDIO User PHY Select Register 0 (MDIOUSERPHYSEL0)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 14-262. MDIO User PHY Select Register 0 (MDIOUSERPHYSEL0) Field Descriptions**

Bit	Field	Value	Description
31-8	Reserved	0	Reserved.
7	LINKSEL	0-1	Link status determination select. Set to 1 to determine link status using the MLINK pin. Default value is 0 which implies that the link status is determined by the MDIO state machine.
6	LINKINTENB	0 1	Link change interrupt enable. Set to 1 to enable link change status interrupts for PHY address specified in PHYADDRMON. Link change interrupts are disabled if this bit is set to 0. Link change interrupts are disabled. Link change status interrupts for PHY address specified in PHYADDRMON bits are enabled.
5	Reserved	0	Reserved.
4-0	PHYADDRMON	0-1Fh	PHY address whose link status is to be monitored.

### 14.5.10.13 MDIO User Access Register 1 (MDIOUSERACCESS1)

The MDIO user access register 1 (MDIOUSERACCESS1) is shown in [Figure 14-244](#) and described in [Table 14-263](#).

**Figure 14-244. MDIO User Access Register 1 (MDIOUSERACCESS1)**

LEGEND: R/W = Read/Write; R = Read only; S = Status; -n = value after reset

**Table 14-263. MDIO User Access Register 1 (MDIOUSERACCESS1) Field Descriptions**

Bit	Field	Value	Description
31	GO	0-1	Writing a 1 to this bit causes the MDIO state machine to perform an MDIO access when it is convenient for it to do so, this is not an instantaneous process. Writing a 0 to this bit has no effect. This bit is write able only if the MDIO state machine is enabled. This bit will self clear when the requested access has been completed. Any writes to the MDIOUSERACCESS0 register are blocked when the GO bit is 1. If byte access is being used, the GO bit should be written last.
30	WRITE	0-1	Write enable. Setting this bit to a 1 causes the MDIO transaction to be a register write, otherwise it is a register read.
29	ACK	0-1	Acknowledge. This bit is set if the PHY acknowledged the read transaction.
28-26	Reserved	0	Reserved.
25-21	REGADR	0-1Fh	Register address; specifies the PHY register to be accessed for this transaction.
20-16	PHYADR	0-1Fh	PHY address; specifies the PHY to be accesses for this transaction.
15-0	DATA	0-FFFFh	User data. The data value read from or to be written to the specified PHY register.

**14.5.10.14 MDIO User PHY Select Register 1 (MDIOUSERPHYSEL1)**

The MDIO user PHY select register 1 (MDIOUSERPHYSEL1) is shown in [Figure 14-245](#) and described in [Table 14-264](#).

**Figure 14-245. MDIO User PHY Select Register 1 (MDIOUSERPHYSEL1)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 14-264. MDIO User PHY Select Register 1 (MDIOUSERPHYSEL1) Field Descriptions**

Bit	Field	Value	Description
31-8	Reserved	0	Reserved.
7	LINKSEL	0-1	Link status determination select. Set to 1 to determine link status using the MLINK pin. Default value is 0 which implies that the link status is determined by the MDIO state machine.
6	LINKINTENB	0 1	Link change interrupt enable. Set to 1 to enable link change status interrupts for PHY address specified in PHYADDRMON. Link change interrupts are disabled if this bit is cleared to 0. Link change interrupts are disabled Link change status interrupts for PHY address specified in PHYADDRMON bits are enabled.
5	Reserved	0	Reserved.
4-0	PHYADDRMON	0-1Fh	PHY address whose link status is to be monitored.

## ***Pulse-Width Modulation Subsystem (PWMSS)***

---

---

This chapter describes the PWMSS of the device.

<b>Topic</b>	<b>Page</b>
<b>15.1 Pulse-Width Modulation Subsystem (PWMSS) .....</b>	<b>1486</b>
<b>15.2 Enhanced PWM (ePWM) Module .....</b>	<b>1494</b>
<b>15.3 Enhanced Capture (eCAP) Module .....</b>	<b>1607</b>
<b>15.4 Enhanced Quadrature Encoder Pulse (eQEP) Module .....</b>	<b>1650</b>

## 15.1 Pulse-Width Modulation Subsystem (PWMSS)

### 15.1.1 Introduction

#### 15.1.1.1 Features

The general features of the PWMSS are:

##### eHRPWM

- Dedicated 16 bit time-base with Period / Frequency control
- Can support 2 independent PWM outputs with Single edge operation
- Can support 2 independent PWM outputs with Dual edge symmetric operation
- Can support 1 independent PWM output with Dual edge asymmetric operation
- Supports Dead-band generation with independent Rising and Falling edge delay control
- Provides asynchronous over-ride control of PWM signals during fault conditions
- Supports “trip zone” allocation of both latched and un-latched fault conditions
- Allows events to trigger both CPU interrupts and start of ADC conversions
- Support PWM chopping by high frequency carrier signal, used for pulse transformer gate drives.
- High-resolution module with programmable delay line.
  - Programmable on a per PWM period basis.
  - Can be inserted either on the rising edge or falling edge of the PWM pulse or both or not at all.

##### eCAP

- Dedicated input Capture pin
- 32 bit Time Base (counter)
- 4 x 32 bit Time-stamp Capture registers (CAP1-CAP4)
- 4 stage sequencer (Mod4 counter) which is synchronized to external events (ECAPx pin edges)
- Independent Edge polarity (Rising / Falling edge) selection for all 4 events
- Input Capture signal pre-scaling (from 1 to 16)
- One-shot compare register (2 bits) to freeze captures after 1 to 4 Time-stamp events
- Control for continuous Time-stamp captures using a 4 deep circular buffer (CAP1-CAP4) scheme
- Interrupt capabilities on any of the 4 capture events

##### eQEP

- Input Synchronization
- Three Stage/Six Stage Digital Noise Filter
- Quadrature Decoder Unit
- Position Counter and Control unit for position measurement
- Quadrature Edge Capture unit for low speed measurement
- Unit Time base for speed/frequency measurement
- Watchdog Timer for detecting stalls

### 15.1.1.2 Unsupported Features

The PWMSS module features not supported are shown in [Table 15-1](#).

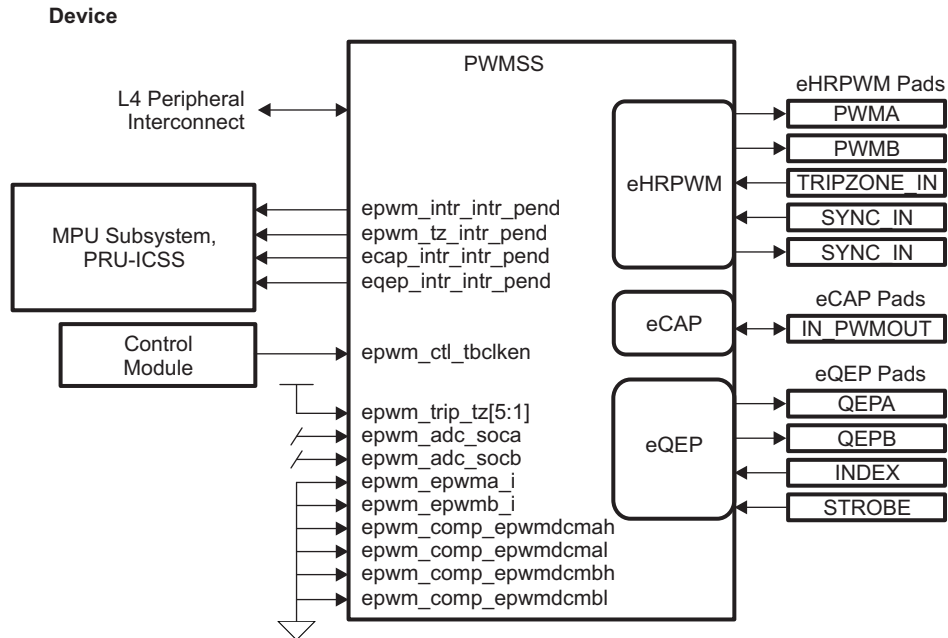

**Table 15-1. Unsupported Features**

<b>Feature</b>	<b>Reason</b>
ePWM inputs	Not pinned out
ePWM tripzone 1-5 inputs	Only Tripzone0 is pinned out
ePWM digital comparators	Inputs not connected
eQEP quadrature outputs	Only input signals are connected

### 15.1.2 Integration

The Pulse Width Modulation Subsystem (PWMSS) includes a single instance of the Enhanced High Resolution Pulse Width Modulator (eHRPWM), Enhanced Capture (eCAP), and Enhanced Quadrature Encoded Pulse (eQEP) modules. This includes three instantiations of the PWMSS.

**Figure 15-1. PWMSS Integration**

#### 15.1.2.1 PWMSS Connectivity Attributes

The general connectivity attributes for the PWMSS module are shown in [Table 15-2](#).

**Table 15-2. PWMSS Connectivity Attributes**

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L4LS_GCLK
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	<p>2 ePWM interrupts per instance</p> <ul style="list-style-type: none"> <li><code>epwm_intr_intr</code> - Event interrupt, ePWMxINT for ARM subsystem, <code>epwm_intr_intr_pend</code> for PRU-ICSS</li> <li><code>epwm_tz_intr</code> - Tripzone interrupt, ePWMx_TZINT for ARM subsystem, <code>pwm_trip_zone</code> for PRU-ICSS (only 1 for all 3 instances)</li> </ul> <p>1 eCAP interrupt per instance</p> <ul style="list-style-type: none"> <li><code>ecap_intr</code> - Capture/PWM event interrupt, eCAPxINT for ARM subsystem, <code>ecap_intr_intr_pend</code> for PRU-ICSS</li> </ul> <p>1 eQEP Interrupt per instance</p> <ul style="list-style-type: none"> <li><code>eqep_intr_intr</code> - Event interrupt, eQEPxINT for ARM subsystem, <code>eqep_intr_intr_pend</code> for PRU-ICSS (only for eQEP0)</li> </ul>
DMA Requests	<p>Interrupt requests are redirected as DMA requests:</p> <ul style="list-style-type: none"> <li>1 DMA request from ePWM per instance (ePWMEVTx)</li> <li>1 DMA request from eCAP per instance (eCAPEVTx)</li> <li>1 DMA request from eQEP per instance (eQEPEVTx)</li> </ul>
Physical Address	L4 Peripheral slave port

### 15.1.2.2 PWMSS Clock and Reset Management

The PWMSS controllers have separate bus interface and functional clocks.

**Table 15-3. PWMSS Clock Signals**

Clock Signal	Max Freq	Reference / Source	Comments
PWMSS_ocp_clk Interface / Functional clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l4ls_gclk from PRCM

### 15.1.2.3 PWMSS Pin list

The external signals for the PWMSS module are shown in the following table.

**Table 15-4. PWMSS Pin List**

Pin	Type*	Description
EPWMxA	O	PWM output A
EPWMxB	O	PWM output B
EPWM_SYNCIN	I	PWM Sync input
EPWM_SYNCOUT	O	PWM Sync output
EPWM_TRIPZONE[5:0]	I	PWM Tripzone inputs
ECAP_CAPIN_APWMOUT	I/O	eCAP Capture input / PWM output
EQEP_A	I/O	eQEP Quadrature input/output
EQEP_B	I/O	eQEP Quadrature input/output
EQEP_INDEX	I/O	eQEP Index input/output
EQEP_STROBE	I/O	eQEP Strobe input/output

### 15.1.3 PWMSS Registers

[Table 15-5](#) lists the memory-mapped registers for the PWMSS. All register offset addresses not listed in [Table 15-5](#) should be considered as reserved locations and the register contents should not be modified.

**Table 15-5. PWMSS REGISTERS**

Offset	Acronym	Register Name	Section
0h	IDVER	IP Revision Register	<a href="#">Section 15.1.3.1</a>
4h	SYSCONFIG	System Configuration Register	<a href="#">Section 15.1.3.2</a>
8h	CLKCONFIG	Clock Configuration Register	<a href="#">Section 15.1.3.3</a>
Ch	CLKSTATUS	Clock Status Register	<a href="#">Section 15.1.3.4</a>

### 15.1.3.1 IDVER Register (offset = 0h) [reset = 4000000h]

IDVER is shown in [Figure 15-2](#) and described in [Table 15-6](#).

The IP revision register is used by software to track features, bugs, and compatibility.

**Figure 15-2. IDVER Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 15-6. IDVER Register Field Descriptions**

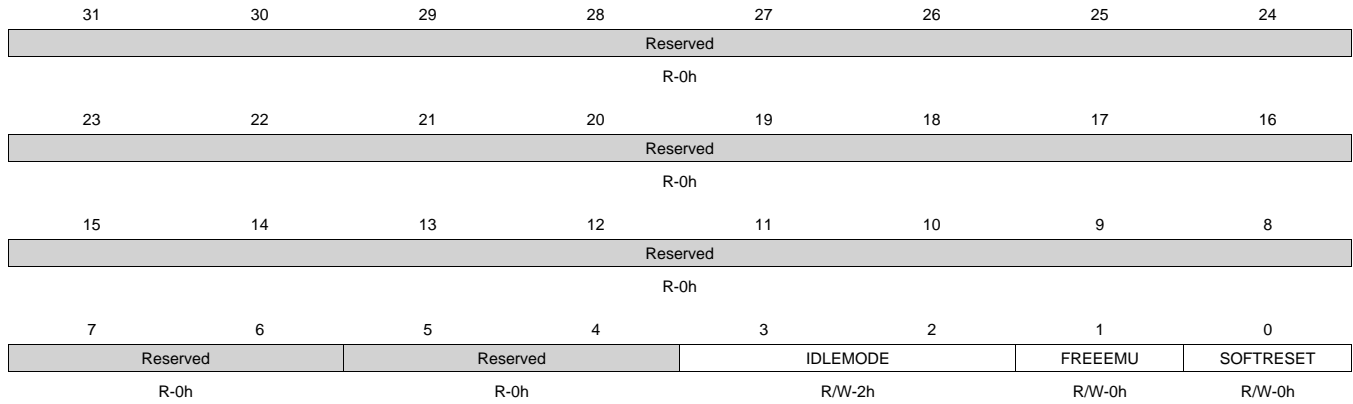

Bit	Field	Type	Reset	Description
31-30	SCHEME	R	1h	Used to distinguish between the old scheme and current.
29-28	Reserved	R	0h	
27-16	FUNC	R	0h	FUNC
15-11	R RTL	R	0h	RTL version (R), maintained by IP design owner.
10-8	X MAJOR	R	0h	Major revision (X)
7-6	CUSTOM	R	0h	CUSTOM
5-0	Y MINOR	R	0h	Minor revision (Y)

### 15.1.3.2 SYSCONFIG Register (offset = 4h) [reset = 28h]

SYSCONFIG is shown in [Figure 15-3](#) and described in [Table 15-7](#).

The system configuration register is used for clock management configuration.

**Figure 15-3. SYSCONFIG Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 15-7. SYSCONFIG Register Field Descriptions**

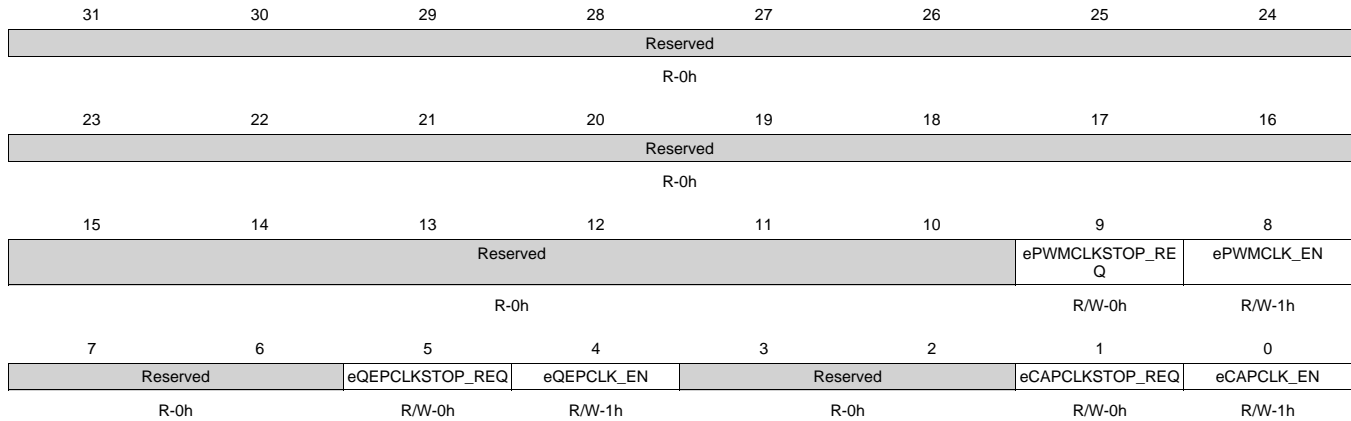

Bit	Field	Type	Reset	Description
31-6	Reserved	R	0h	
5-4	Reserved	R	0h	
3-2	IDLEMODE	R/W	2h	Configuration of the local target state management mode. By definition, target can handle read/write transaction as long as it is out of IDLE state. 0x0 = Force-idle mode: local target's idle state follows (acknowledges) the system's idle requests unconditionally, i.e. regardless of the IP module's internal requirements. Backup mode, for debug only. 0x1 = No-idle mode: local target never enters idle state. Backup mode, for debug only. 0x2 = Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module shall not generate (IRQ- or DMA-request-related) wakeup events. 0x3 = Reserved.
1	FREEEMU	R/W	0h	Sensitivity to emulation (debug) suspend input signal. 0x0 = IP module is sensitive to emulation suspend. 0x1 = IP module is not sensitive to emulation suspend.
0	SOFTRESET	R/W	0h	Software reset (optional)

### 15.1.3.3 CLKCONFIG Register (offset = 8h) [reset = 111h]

CLKCONFIG is shown in [Figure 15-4](#) and described in [Table 15-8](#).

The clock configuration register is used in the PWMSS submodule for clkstop req and clk\_en control.

**Figure 15-4. CLKCONFIG Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 15-8. CLKCONFIG Register Field Descriptions**

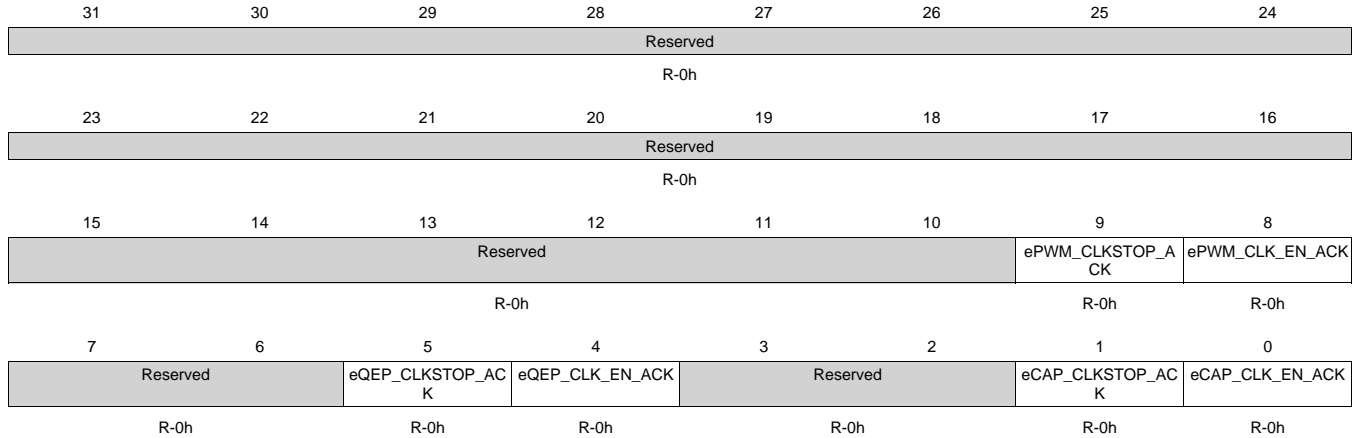

Bit	Field	Type	Reset	Description
31-10	Reserved	R	0h	
9	ePWMCLKSTOP_REQ	R/W	0h	This bit controls the clkstop_req input to the ePWM module.
8	ePWMCLK_EN	R/W	1h	This bit controls the clk_en input to the ePWM module.
7-6	Reserved	R	0h	
5	eQEPClkSTOP_REQ	R/W	0h	This bit controls the clkstop_req input to the eQEP module
4	eQEPClk_EN	R/W	1h	This bit controls the clk_en input to the eQEP module.
3-2	Reserved	R	0h	
1	eCAPCLKSTOP_REQ	R/W	0h	This bit controls the clkstop_req input to the eCAP module.
0	eCAPCLK_EN	R/W	1h	This bit controls the clk_en input to the eCAP module.

### 15.1.3.4 CLKSTATUS Register (offset = Ch) [reset = 0h]

CLKSTATUS is shown in [Figure 15-5](#) and described in [Table 15-9](#).

The clock status register is used in the PWMSS submodule for clkstop ack and clk\_en ack status.

**Figure 15-5. CLKSTATUS Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 15-9. CLKSTATUS Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-10	Reserved	R	0h	
9	ePWM_CLKSTOP_ACK	R	0h	This bit is the clkstop_req_ack status output of the ePWM module.
8	ePWM_CLK_EN_ACK	R	0h	This bit is the clk_en status output of the ePWM module.
7-6	Reserved	R	0h	
5	eQEP_CLKSTOP_ACK	R	0h	This bit is the clkstop_req_ack status output of the eQEP module.
4	eQEP_CLK_EN_ACK	R	0h	This bit is the clk_en status output of the eQEP module.
3-2	Reserved	R	0h	
1	eCAP_CLKSTOP_ACK	R	0h	This bit is the clkstop_req_ack status output of the eCAP module.
0	eCAP_CLK_EN_ACK	R	0h	This bit is the clk_en status output of the eCAP module.

## 15.2 Enhanced PWM (ePWM) Module

### 15.2.1 Introduction

An effective PWM peripheral must be able to generate complex pulse width waveforms with minimal CPU overhead or intervention. It needs to be highly programmable and very flexible while being easy to understand and use. The ePWM unit described here addresses these requirements by allocating all needed timing and control resources on a per PWM channel basis. Cross coupling or sharing of resources has been avoided; instead, the ePWM is built up from smaller single channel modules with separate resources and that can operate together as required to form a system. This modular approach results in an orthogonal architecture and provides a more transparent view of the peripheral structure, helping users to understand its operation quickly.

In this chapter, the letter x within a signal or module name is used to indicate a generic ePWM instance on a device. For example, output signals EPWMxA and EPWMxB refer to the output signals from the ePWMx instance. Thus, EPWM1A and EPWM1B belong to ePWM1 and, likewise, EPWM4A and EPWM4B belong to ePWM4.

#### 15.2.1.1 Submodule Overview

The ePWM module represents one complete PWM channel composed of two PWM outputs: EPWMxA and EPWMxB. Multiple ePWM modules are instanced within a device as shown in [Figure 15-6](#). Each ePWM instance is identical with one exception. Some instances include a hardware extension that allows more precise control of the PWM outputs. This extension is the high-resolution pulse width modulator (HRPWM) and is described in [Section 15.2.2.10](#). See [Section 15.1.2](#) to determine which ePWM instances include this feature. Each ePWM module is indicated by a numerical value starting with 1. For example ePWM0 is the first instance and ePWM2 is the third instance in the system and ePWMx indicates any instance.

The ePWM modules are chained together via a clock synchronization scheme that allows them to operate as a single system when required. Additionally, this synchronization scheme can be extended to the capture peripheral modules (eCAP). The number of modules is device-dependent and based on target application needs. Modules can also operate stand-alone.

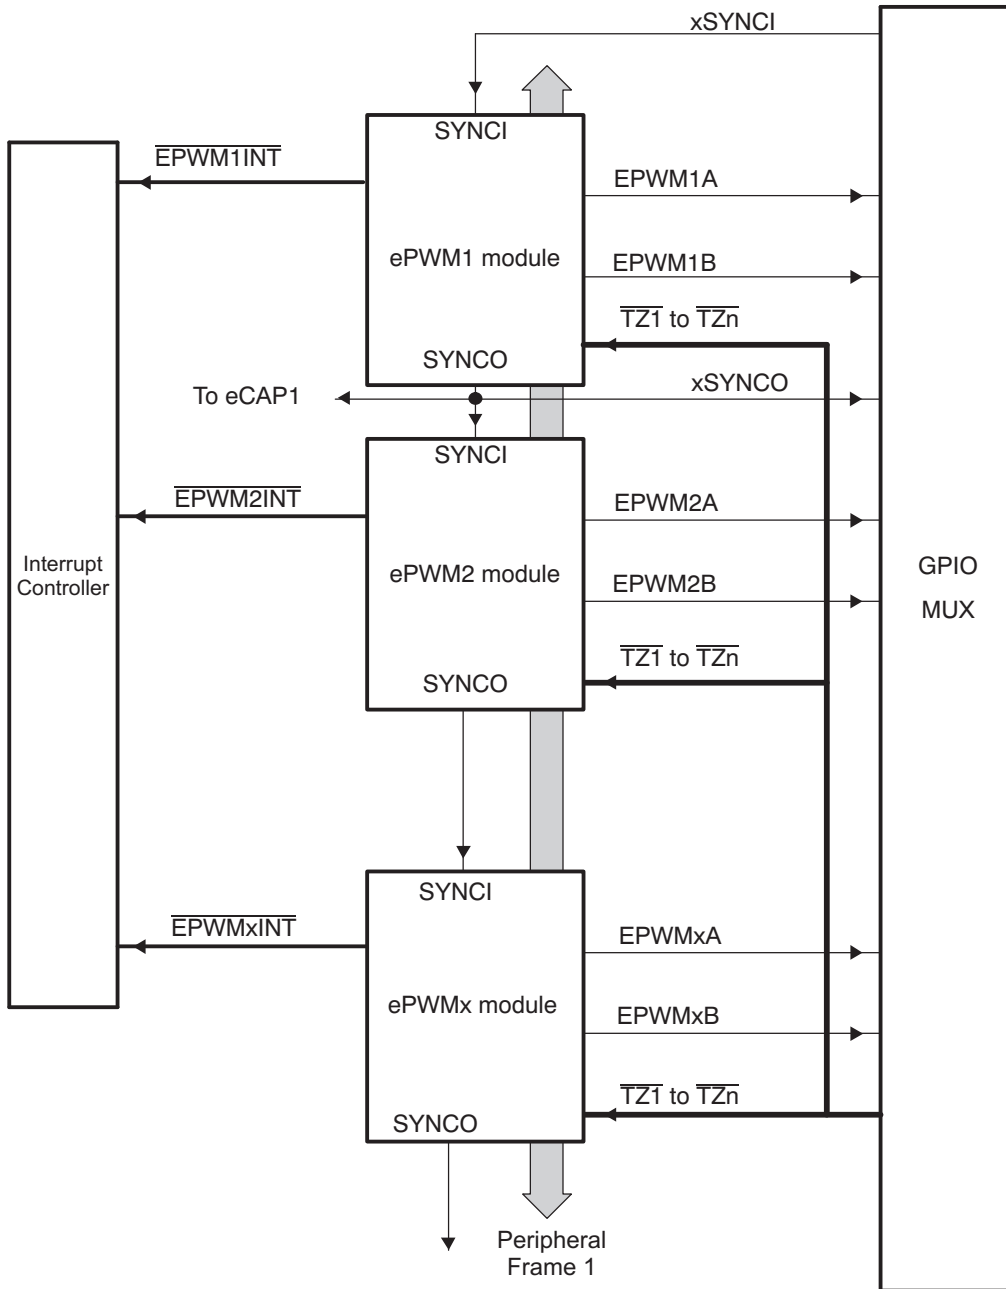

Each ePWM module supports the following features:

- Dedicated 16-bit time-base counter with period and frequency control
- Two PWM outputs (EPWMxA and EPWMxB) that can be used in the following configurations::
  - Two independent PWM outputs with single-edge operation
  - Two independent PWM outputs with dual-edge symmetric operation
  - One independent PWM output with dual-edge asymmetric operation
- Asynchronous override control of PWM signals through software.
- Programmable phase-control support for lag or lead operation relative to other ePWM modules.
- Hardware-locked (synchronized) phase relationship on a cycle-by-cycle basis.
- Dead-band generation with independent rising and falling edge delay control.
- Programmable trip zone allocation of both cycle-by-cycle trip and one-shot trip on fault conditions.
- A trip condition can force either high, low, or high-impedance state logic levels at PWM outputs.
- Programmable event prescaling minimizes CPU overhead on interrupts.
- PWM chopping by high-frequency carrier signal, useful for pulse transformer gate drives.

Each ePWM module is connected to the input/output signals shown in [Figure 15-6](#). The signals are described in detail in subsequent sections.

The order in which the ePWM modules are connected may differ from what is shown in [Figure 15-6](#). See [Section 15.2.2.3.3.2](#) for the synchronization scheme for a particular device. Each ePWM module consists of seven submodules and is connected within a system via the signals shown in [Figure 15-7](#).

Figure 15-6. Multiple ePWM Modules

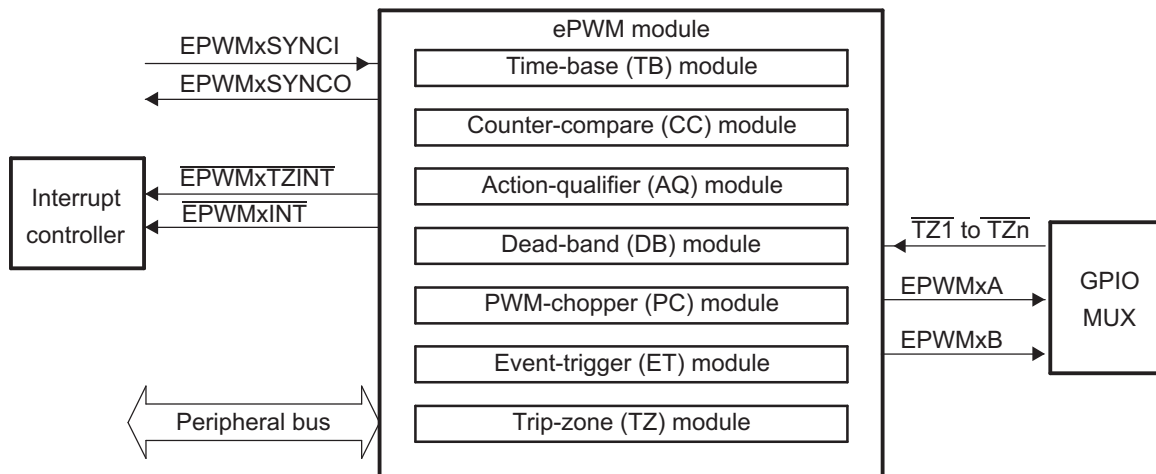

**Figure 15-7. Submodules and Signal Connections for an ePWM Module**

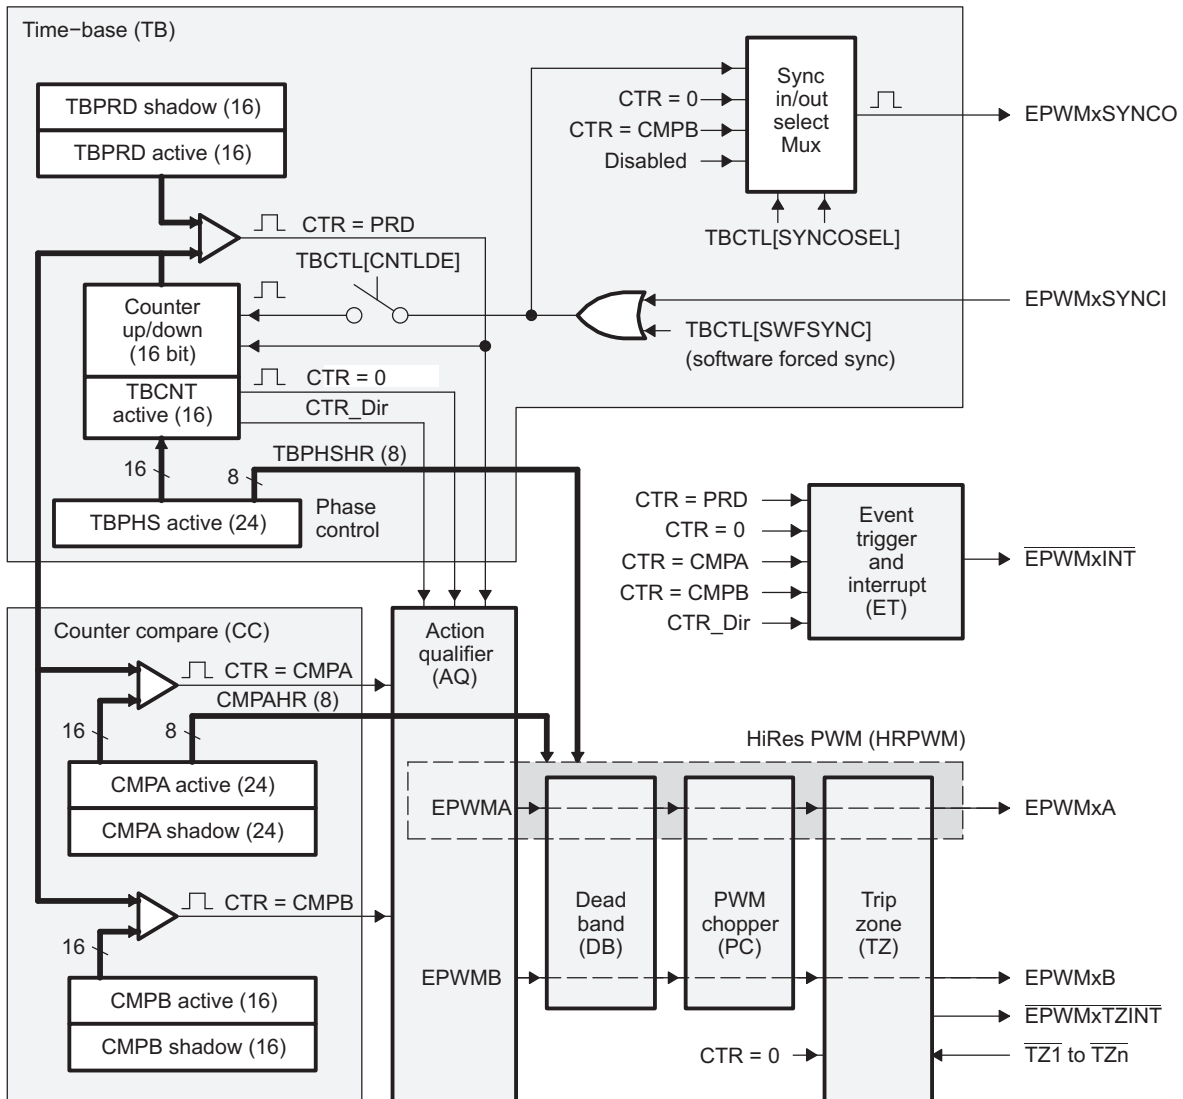

Figure 15-8 shows more internal details of a single ePWM module. The main signals used by the ePWM module are:

- **PWM output signals (EPWMxA and EPWMxB).** The PWM output signals are made available external to the device through the GPIO peripheral described in the system control and interrupts guide for your device.
- **Trip-zone signals ( $\overline{TZ1}$  to  $\overline{TZn}$ ).** These input signals alert the ePWM module of an external fault condition. Each module on a device can be configured to either use or ignore any of the trip-zone signals. The trip-zone signal can be configured as an asynchronous input through the GPIO peripheral. See Section 15.1.2 to determine how many trip-zone pins are available in the device.
- **Time-base synchronization input (EPWMxSYNCl) and output (EPWMxSYNCO) signals.** The synchronization signals daisy chain the ePWM modules together. Each module can be configured to either use or ignore its synchronization input. The clock synchronization input and output signal are brought out to pins only for ePWM1 (ePWM module #1). The synchronization output for ePWM1 (EPWM1SYNCO) is also connected to the SYNCl of the first enhanced capture module (eCAP1).
- **Peripheral Bus.** The peripheral bus is 32-bits wide and allows both 16-bit and 32-bit writes to the ePWM register file.

Figure 15-8 also shows the key internal submodule interconnect signals. Each submodule is described in Section 15.2.2.

Figure 15-8. ePWM Submodules and Critical Internal Signal Interconnects

## 15.2.2 Functional Description

Seven submodules are included in every ePWM peripheral. There are some instances that include a high-resolution submodule that allows more precise control of the PWM outputs. Each of these submodules performs specific tasks that can be configured by software.

### 15.2.2.1 Overview

Table 15-10 lists the eight key submodules together with a list of their main configuration parameters. For example, if you need to adjust or control the duty cycle of a PWM waveform, then you should see the counter-compare submodule in Section 15.2.2.4 for relevant details.

**Table 15-10. Submodule Configuration Parameters**

Submodule	Configuration Parameter or Option
Time-base (TB)	<ul style="list-style-type: none"> <li>• Scale the time-base clock (TBCLK) relative to the system clock (SYSCLKOUT).</li> <li>• Configure the PWM time-base counter (TBCNT) frequency or period.</li> <li>• Set the mode for the time-base counter:                             <ul style="list-style-type: none"> <li>– count-up mode: used for asymmetric PWM</li> <li>– count-down mode: used for asymmetric PWM</li> <li>– count-up-and-down mode: used for symmetric PWM</li> </ul> </li> <li>• Configure the time-base phase relative to another ePWM module.</li> <li>• Synchronize the time-base counter between modules through hardware or software.</li> <li>• Configure the direction (up or down) of the time-base counter after a synchronization event.</li> <li>• Configure how the time-base counter will behave when the device is halted by an emulator.</li> <li>• Specify the source for the synchronization output of the ePWM module:                             <ul style="list-style-type: none"> <li>– Synchronization input signal</li> <li>– Time-base counter equal to zero</li> <li>– Time-base counter equal to counter-compare B (CMPB)</li> <li>– No output synchronization signal generated.</li> </ul> </li> </ul>
Counter-compare (CC)	<ul style="list-style-type: none"> <li>• Specify the PWM duty cycle for output EPWMxA and/or output EPWMxB</li> <li>• Specify the time at which switching events occur on the EPWMxA or EPWMxB output</li> </ul>
Action-qualifier (AQ)	<ul style="list-style-type: none"> <li>• Specify the type of action taken when a time-base or counter-compare submodule event occurs:                             <ul style="list-style-type: none"> <li>– No action taken</li> <li>– Output EPWMxA and/or EPWMxB switched high</li> <li>– Output EPWMxA and/or EPWMxB switched low</li> <li>– Output EPWMxA and/or EPWMxB toggled</li> </ul> </li> <li>• Force the PWM output state through software control</li> <li>• Configure and control the PWM dead-band through software</li> </ul>
Dead-band (DB)	<ul style="list-style-type: none"> <li>• Control of traditional complementary dead-band relationship between upper and lower switches</li> <li>• Specify the output rising-edge-delay value</li> <li>• Specify the output falling-edge delay value</li> <li>• Bypass the dead-band module entirely. In this case the PWM waveform is passed through without modification.</li> </ul>
PWM-chopper (PC)	<ul style="list-style-type: none"> <li>• Create a chopping (carrier) frequency.</li> <li>• Pulse width of the first pulse in the chopped pulse train.</li> <li>• Duty cycle of the second and subsequent pulses.</li> <li>• Bypass the PWM-chopper module entirely. In this case the PWM waveform is passed through without modification.</li> </ul>

**Table 15-10. Submodule Configuration Parameters (continued)**

Submodule	Configuration Parameter or Option
Trip-zone (TZ)	<ul style="list-style-type: none"> <li>• Configure the ePWM module to react to one, all, or none of the trip-zone pins.</li> <li>• Specify the tripping action taken when a fault occurs: <ul style="list-style-type: none"> <li>– Force EPWMxA and/or EPWMxB high</li> <li>– Force EPWMxA and/or EPWMxB low</li> <li>– Force EPWMxA and/or EPWMxB to a high-impedance state</li> <li>– Configure EPWMxA and/or EPWMxB to ignore any trip condition.</li> </ul> </li> <li>• Configure how often the ePWM will react to each trip-zone pin: <ul style="list-style-type: none"> <li>– One-shot</li> <li>– Cycle-by-cycle</li> </ul> </li> <li>• Enable the trip-zone to initiate an interrupt.</li> <li>• Bypass the trip-zone module entirely.</li> </ul>
Event-trigger (ET)	<ul style="list-style-type: none"> <li>• Enable the ePWM events that will trigger an interrupt.</li> <li>• Specify the rate at which events cause triggers (every occurrence or every second or third occurrence)</li> <li>• Poll, set, or clear event flags</li> </ul>
High-Resolution PWM (HRPWM)	<ul style="list-style-type: none"> <li>• Enable extended time resolution capabilities</li> <li>• Configure finer time granularity control or edge positioning</li> </ul>

Code examples are provided in the remainder of this chapter that show how to implement various ePWM module configurations. These examples use the constant definitions shown in [Example 15-1](#).

#### **Example 15-1. Constant Definitions Used in the Code Examples**

```
// TBCTL (Time-Base Control)
// = = = = =
// TBCNT MODE bits
#define TB_COUNT_UP          0x0
#define TB_COUNT_DOWN       0x1

```

**15.2.2.2 Proper Interrupt Initialization Procedure**

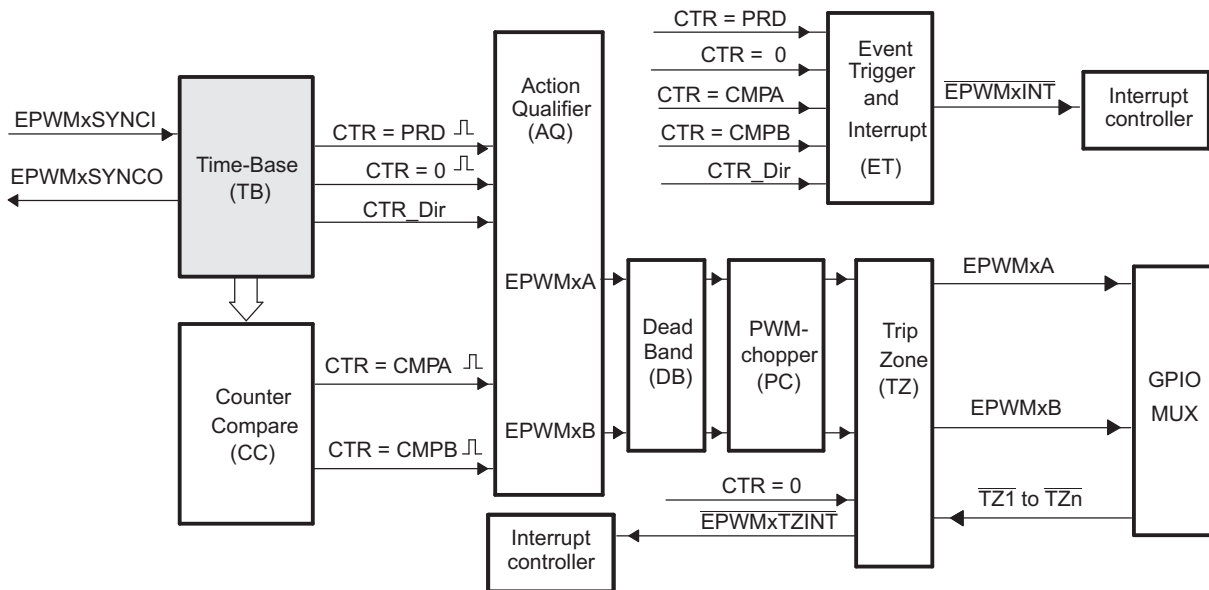

When the ePWM peripheral clock is enabled it may be possible that interrupt flags may be set due to spurious events due to the ePWM registers not being properly initialized. The proper procedure for initializing the ePWM peripheral is:

1. Disable global interrupts (CPU INTM flag)
2. Disable ePWM interrupts
3. Initialize peripheral registers
4. Clear any spurious ePWM flags
5. Enable ePWM interrupts
6. Enable global interrupts

**15.2.2.3 Time-Base (TB) Submodule**

Each ePWM module has its own time-base submodule that determines all of the event timing for the ePWM module. Built-in synchronization logic allows the time-base of multiple ePWM modules to work together as a single system. Figure 15-9 illustrates the time-base module's place within the ePWM.

**Figure 15-9. Time-Base Submodule Block Diagram**

### 15.2.2.3.1 Purpose of the Time-Base Submodule

You can configure the time-base submodule for the following:

- Specify the ePWM time-base counter (TBCNT) frequency or period to control how often events occur.
- Manage time-base synchronization with other ePWM modules.
- Maintain a phase relationship with other ePWM modules.
- Set the time-base counter to count-up, count-down, or count-up-and-down mode.
- Generate the following events:
  - CTR = PRD: Time-base counter equal to the specified period (TBCNT = TBPRD) .
  - CTR = 0: Time-base counter equal to zero (TBCNT = 0000h).
- Configure the rate of the time-base clock; a prescaled version of the CPU system clock (SYSCLKOUT). This allows the time-base counter to increment/decrement at a slower rate.

15.2.2.3.2 Controlling and Monitoring the Time-Base Submodule

Table 15-11 lists the registers used to control and monitor the time-base submodule.

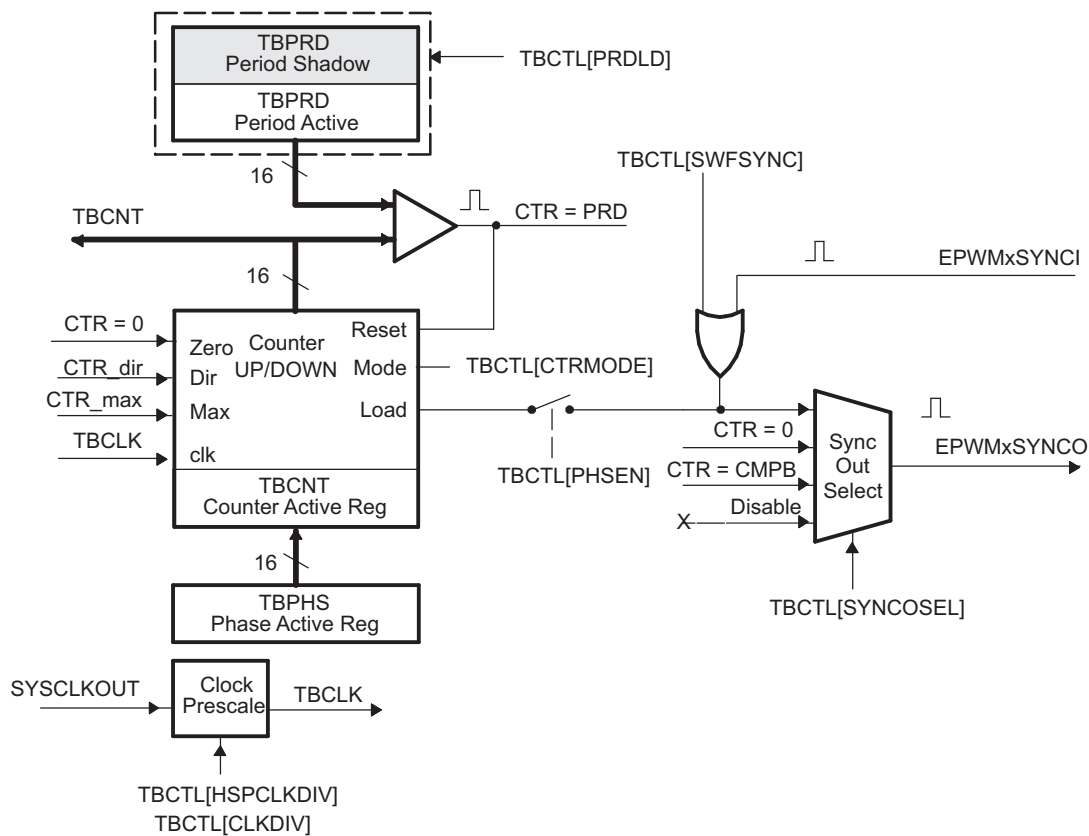

Table 15-11. Time-Base Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
TBCTL	Time-Base Control Register	0h	No
TBSTS	Time-Base Status Register	2h	No
TBPHSHR	HRPWM extension Phase Register <sup>(1)</sup>	4h	No
TBPHS	Time-Base Phase Register	6h	No
TBCNT	Time-Base Counter Register	8h	No
TBPRD	Time-Base Period Register	Ah	Yes

<sup>(1)</sup> This register is available only on ePWM instances that include the high-resolution extension (HRPWM). On ePWM modules that do not include the HRPWM, this location is reserved. See Section 15.1.2 to determine which ePWM instances include this feature.

Figure 15-10 shows the critical signals and registers of the time-base submodule. Table 15-12 provides descriptions of the key signals associated with the time-base submodule.

Figure 15-10. Time-Base Submodule Signals and Registers

**Table 15-12. Key Time-Base Signals**

Signal	Description
EPWMxSYNCl	Time-base synchronization input.  Input pulse used to synchronize the time-base counter with the counter of ePWM module earlier in the synchronization chain. An ePWM peripheral can be configured to use or ignore this signal. For the first ePWM module (EPWM1) this signal comes from a device pin. For subsequent ePWM modules this signal is passed from another ePWM peripheral. For example, EPWM2SYNCl is generated by the ePWM1 peripheral, EPWM3SYNCl is generated by ePWM2 and so forth. See <a href="#">Section 15.2.2.3.3.2</a> for information on the synchronization order of a particular device.
EPWMxSYNCO	Time-base synchronization output.  This output pulse is used to synchronize the counter of an ePWM module later in the synchronization chain. The ePWM module generates this signal from one of three event sources: <ol style="list-style-type: none"> <li>1. EPWMxSYNCl (Synchronization input pulse)</li> <li>2. CTR = 0: The time-base counter equal to zero (TBCNT = 0000h).</li> <li>3. CTR = CMPB: The time-base counter equal to the counter-compare B (TBCNT = CMPB) register.</li> </ol>
CTR = PRD	Time-base counter equal to the specified period.  This signal is generated whenever the counter value is equal to the active period register value. That is when TBCNT = TBPRD.
CTR = 0	Time-base counter equal to zero.  This signal is generated whenever the counter value is zero. That is when TBCNT equals 0000h.
CTR = CMPB	Time-base counter equal to active counter-compare B register (TBCNT = CMPB).  This event is generated by the counter-compare submodule and used by the synchronization out logic.
CTR_dir	Time-base counter direction.  Indicates the current direction of the ePWM's time-base counter. This signal is high when the counter is increasing and low when it is decreasing.
CTR_max	Time-base counter equal max value. (TBCNT = FFFFh)  Generated event when the TBCNT value reaches its maximum value. This signal is only used only as a status bit.
TBCLK	Time-base clock.  This is a prescaled version of the system clock (SYSCLKOUT) and is used by all submodules within the ePWM. This clock determines the rate at which time-base counter increments or decrements.

### 15.2.2.3.3 Calculating PWM Period and Frequency

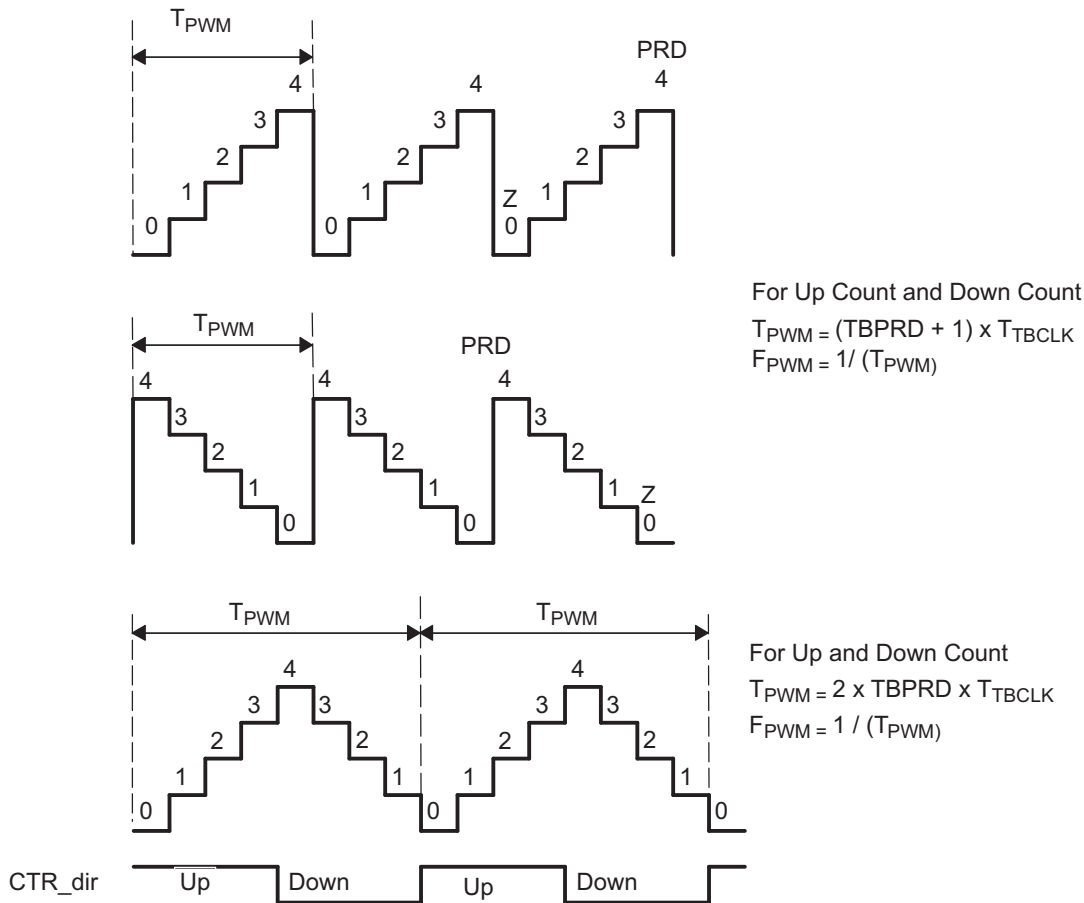

The frequency of PWM events is controlled by the time-base period (TBPRD) register and the mode of the time-base counter. [Figure 15-11](#) shows the period ( $T_{pwm}$ ) and frequency ( $F_{pwm}$ ) relationships for the up-count, down-count, and up-down-count time-base counter modes when the period is set to 4 (TBPRD = 4). The time increment for each step is defined by the time-base clock (TBCLK) which is a prescaled version of the system clock (SYSCLKOUT).

The time-base counter has three modes of operation selected by the time-base control register (TBCTL):

- **Up-Down-Count Mode:** In up-down-count mode, the time-base counter starts from zero and increments until the period (TBPRD) value is reached. When the period value is reached, the time-base counter then decrements until it reaches zero. At this point the counter repeats the pattern and begins to increment.
- **Up-Count Mode:** In this mode, the time-base counter starts from zero and increments until it reaches the value in the period register (TBPRD). When the period value is reached, the time-base counter resets to zero and begins to increment once again.
- **Down-Count Mode:** In down-count mode, the time-base counter starts from the period (TBPRD) value and decrements until it reaches zero. When it reaches zero, the time-base counter is reset to the period value and it begins to decrement once again.

Figure 15-11. Time-Base Frequency and Period

### 15.2.2.3.3.1 Time-Base Period Shadow Register

The time-base period register (TBPRD) has a shadow register. Shadowing allows the register update to be synchronized with the hardware. The following definitions are used to describe all shadow registers in the ePWM module:

- **Active Register:** The active register controls the hardware and is responsible for actions that the hardware causes or invokes.
- **Shadow Register:** The shadow register buffers or provides a temporary holding location for the active register. It has no direct effect on any control hardware. At a strategic point in time the shadow register's content is transferred to the active register. This prevents corruption or spurious operation due to the register being asynchronously modified by software.

The memory address of the shadow period register is the same as the active register. Which register is written to or read from is determined by the TBCTL[PRDL] bit. This bit enables and disables the TBPRD shadow register as follows:

- **Time-Base Period Shadow Mode:** The TBPRD shadow register is enabled when TBCTL[PRDL] = 0. Reads from and writes to the TBPRD memory address go to the shadow register. The shadow register contents are transferred to the active register (TBPRD (Active) ← TBPRD (shadow)) when the time-base counter equals zero (TBCNT = 0000h). By default the TBPRD shadow register is enabled.
- **Time-Base Period Immediate Load Mode:** If immediate load mode is selected (TBCTL[PRDL] = 1), then a read from or a write to the TBPRD memory address goes directly to the active register.

### 15.2.2.3.3.2 Time-Base Counter Synchronization

A time-base synchronization scheme connects all of the ePWM modules on a device. Each ePWM module has a synchronization input (EPWMxSYNCl) and a synchronization output (EPWMxSYNCO). The input synchronization for the first instance (ePWM1) comes from an external pin. The possible synchronization connections for the remaining ePWM modules is shown in [Figure 15-12](#).

**Figure 15-12. Time-Base Counter Synchronization Scheme 1**

Each ePWM module can be configured to use or ignore the synchronization input. If the TBCTL[PHSEN] bit is set, then the time-base counter (TBCNT) of the ePWM module will be automatically loaded with the phase register (TBPHS) contents when one of the following conditions occur:

- **EPWMxSYNCl: Synchronization Input Pulse:** The value of the phase register is loaded into the counter register when an input synchronization pulse is detected (TBPHS → TBCNT). This operation occurs on the next valid time-base clock (TBCLK) edge.
- **Software Forced Synchronization Pulse:** Writing a 1 to the TBCTL[SWFSYNC] control bit invokes a software forced synchronization. This pulse is ORed with the synchronization input signal, and therefore has the same effect as a pulse on EPWMxSYNCl.

This feature enables the ePWM module to be automatically synchronized to the time base of another ePWM module. Lead or lag phase control can be added to the waveforms generated by different ePWM modules to synchronize them. In up-down-count mode, the TBCTL[PSHDIR] bit configures the direction of the time-base counter immediately after a synchronization event. The new direction is independent of the direction prior to the synchronization event. The TBPHS bit is ignored in count-up or count-down modes. See [Figure 15-13](#) through [Figure 15-16](#) for examples.

Clearing the TBCTL[PHSEN] bit configures the ePWM to ignore the synchronization input pulse. The synchronization pulse can still be allowed to flow-through to the EPWMxSYNCO and be used to synchronize other ePWM modules. In this way, you can set up a master time-base (for example, ePWM1) and downstream modules (ePWM2 - ePWMx) may elect to run in synchronization with the master.

#### 15.2.2.3.4 Phase Locking the Time-Base Clocks of Multiple ePWM Modules

The TBCLKEN bit in the PWMSS\_CTRL register in the Control Module can be used to globally synchronize the time-base clocks of all enabled ePWM modules on a device. The TBCLKEN bit is part of the chip configuration registers and is described in [Chapter 9](#). When TBCLKEN = 0, the time-base clock of all ePWM modules is stopped (default). When TBCLKEN = 1, all ePWM time-base clocks are started with the rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescaler bits in the TBCTL register of each ePWM module must be set identically. The proper procedure for enabling the ePWM clocks is as follows:

1. Enable the ePWM module clocks.
2. Set TBCLKEN = 0. This will stop the time-base clock within any enabled ePWM module.
3. Configure the prescaler values and desired ePWM modes.
4. Set TBCLKEN = 1.

#### 15.2.2.3.5 Time-Base Counter Modes and Timing Waveforms

The time-base counter operates in one of four modes:

- Up-count mode which is asymmetrical.
- Down-count mode which is asymmetrical.
- Up-down-count which is symmetrical.
- Frozen where the time-base counter is held constant at the current value.

To illustrate the operation of the first three modes, [Figure 15-13](#) to [Figure 15-16](#) show when events are generated and how the time-base responds to an EPWMxSYNCl signal.

Figure 15-13. Time-Base Up-Count Mode Waveforms

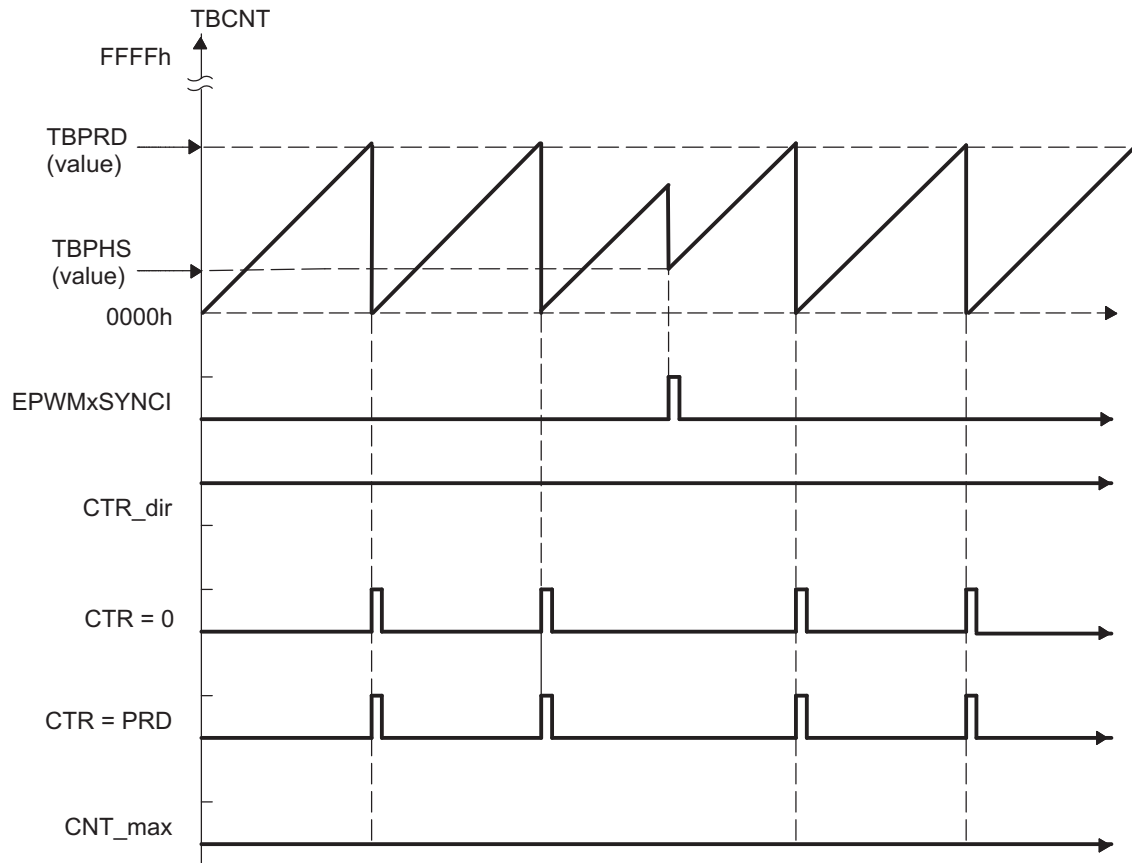

Figure 15-14. Time-Base Down-Count Mode Waveforms

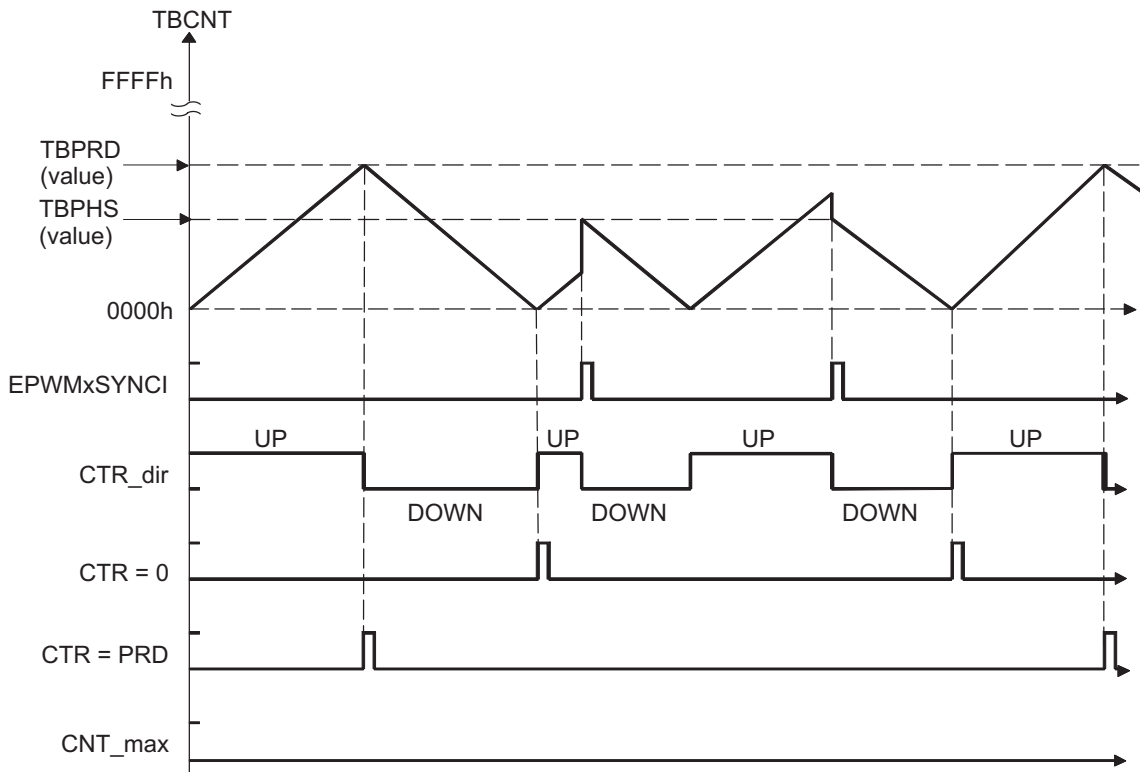

Figure 15-15. Time-Base Up-Down-Count Waveforms, TBCTL[PHSDIR = 0] Count Down on Synchronization Event

**Figure 15-16. Time-Base Up-Down Count Waveforms, TBCTL[PHSDIR = 1] Count Up on Synchronization Event**

15.2.2.4 Counter-Compare (CC) Submodule

Figure 15-17 illustrates the counter-compare submodule within the ePWM. Figure 15-18 shows the basic structure of the counter-compare submodule.

Figure 15-17. Counter-Compare Submodule

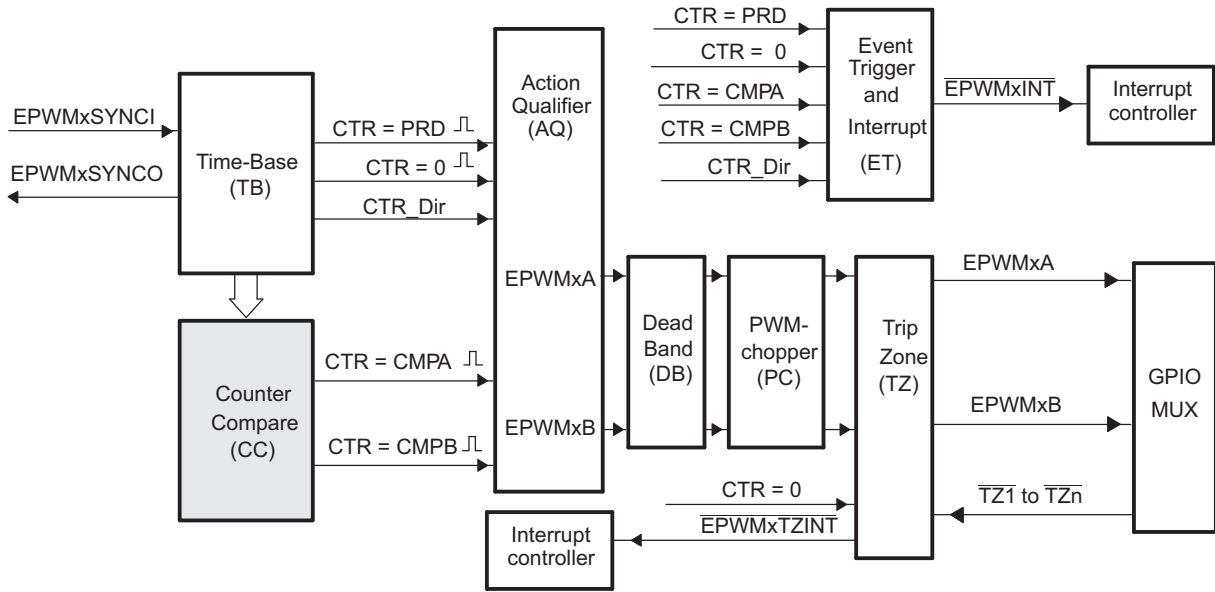

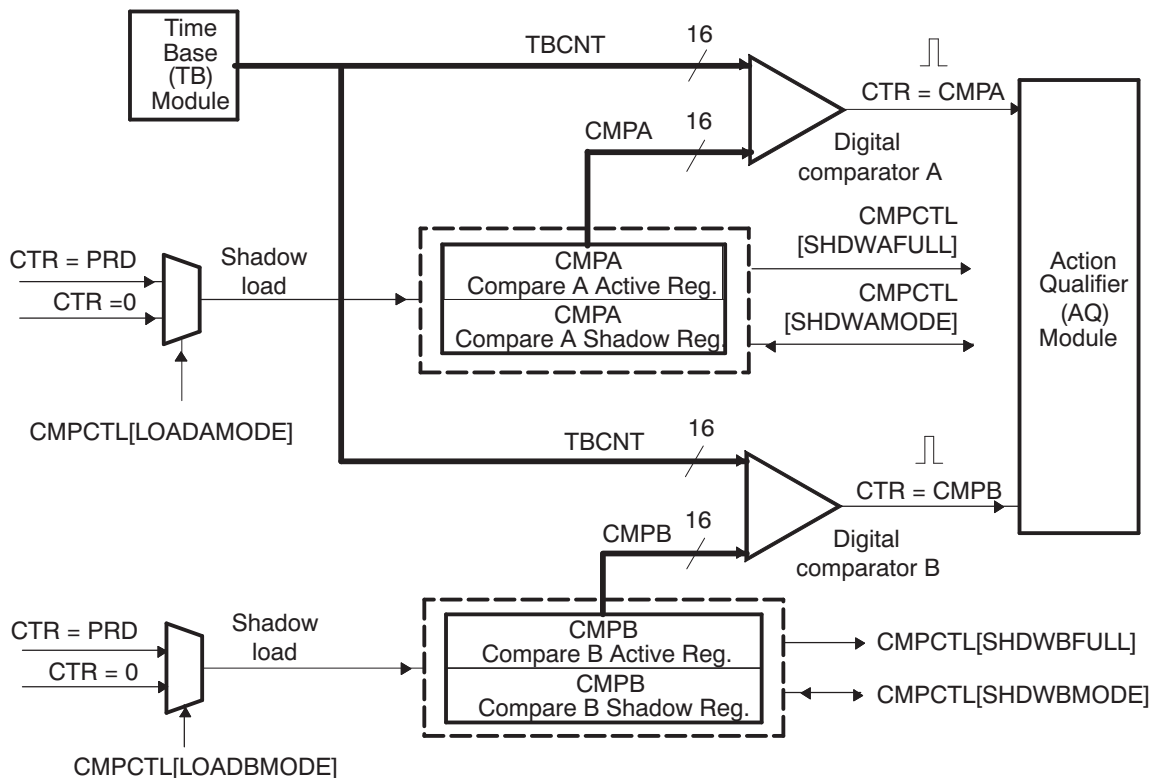

Figure 15-18. Counter-Compare Submodule Signals and Registers

### 15.2.2.4.1 Purpose of the Counter-Compare Submodule

The counter-compare submodule takes as input the time-base counter value. This value is continuously compared to the counter-compare A (CMPA) and counter-compare B (CMPB) registers. When the time-base counter is equal to one of the compare registers, the counter-compare unit generates an appropriate event.

The counter-compare submodule:

- Generates events based on programmable time stamps using the CMPA and CMPB registers
  - CTR = CMPA: Time-base counter equals counter-compare A register (TBCNT = CMPA).
  - CTR = CMPB: Time-base counter equals counter-compare B register (TBCNT = CMPB)
- Controls the PWM duty cycle if the action-qualifier submodule is configured appropriately
- Shadows new compare values to prevent corruption or glitches during the active PWM cycle

### 15.2.2.4.2 Controlling and Monitoring the Counter-Compare Submodule

Table 15-13 lists the registers used to control and monitor the counter-compare submodule. Table 15-14 lists the key signals associated with the counter-compare submodule.

**Table 15-13. Counter-Compare Submodule Registers**

Acronym	Register Description	Address Offset	Shadowed
CMPCTL	Counter-Compare Control Register.	Eh	No
CMPAHR	HRPWM Counter-Compare A Extension Register <sup>(1)</sup>	10h	Yes
CMPA	Counter-Compare A Register	12h	Yes
CMPB	Counter-Compare B Register	14h	Yes

<sup>(1)</sup> This register is available only on ePWM modules with the high-resolution extension (HRPWM). On ePWM modules that do not include the HRPWM, this location is reserved. See Section 15.1.2 to determine which ePWM instances include this feature.

**Table 15-14. Counter-Compare Submodule Key Signals**

Signal	Description of Event	Registers Compared
CTR = CMPA	Time-base counter equal to the active counter-compare A value	TBCNT = CMPA
CTR = CMPB	Time-base counter equal to the active counter-compare B value	TBCNT = CMPB
CTR = PRD	Time-base counter equal to the active period. Used to load active counter-compare A and B registers from the shadow register	TBCNT = TBPRD
CTR = 0	Time-base counter equal to zero. Used to load active counter-compare A and B registers from the shadow register	TBCNT = 0000h

### 15.2.2.4.3 Operational Highlights for the Counter-Compare Submodule

The counter-compare submodule is responsible for generating two independent compare events based on two compare registers:

1. CTR = CMPA: Time-base counter equal to counter-compare A register (TBCNT = CMPA).
2. CTR = CMPB: Time-base counter equal to counter-compare B register (TBCNT = CMPB).

For up-count or down-count mode, each event occurs only once per cycle. For up-down-count mode each event occurs twice per cycle, if the compare value is between 0000h and TBPRD; and occurs once per cycle, if the compare value is equal to 0000h or equal to TBPRD. These events are fed into the action-qualifier submodule where they are qualified by the counter direction and converted into actions if enabled. Refer to [Section 15.2.2.5.1](#) for more details.

The counter-compare registers CMPA and CMPB each have an associated shadow register. Shadowing provides a way to keep updates to the registers synchronized with the hardware. When shadowing is used, updates to the active registers only occurs at strategic points. This prevents corruption or spurious operation due to the register being asynchronously modified by software. The memory address of the active register and the shadow register is identical. Which register is written to or read from is determined by the CMPCTL[SHDWAMODE] and CMPCTL[SHDWBMODE] bits. These bits enable and disable the CMPA shadow register and CMPB shadow register respectively. The behavior of the two load modes is described below:

- **Shadow Mode:** The shadow mode for the CMPA is enabled by clearing the CMPCTL[SHDWAMODE] bit and the shadow register for CMPB is enabled by clearing the CMPCTL[SHDWBMODE] bit. Shadow mode is enabled by default for both CMPA and CMPB.

If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events:

- CTR = PRD: Time-base counter equal to the period (TBCNT = TBPRD).
- CTR = 0: Time-base counter equal to zero (TBCNT = 0000h)
- Both CTR = PRD and CTR = 0

Which of these three events is specified by the CMPCTL[LOADAMODE] and CMPCTL[LOADBMODE] register bits. Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.

- **Immediate Load Mode:** If immediate load mode is selected (TBCTL[SHADWAMODE] = 1 or TBCTL[SHADWBMODE] = 1), then a read from or a write to the register will go directly to the active register.

### 15.2.2.4.4 Count Mode Timing Waveforms

The counter-compare module can generate compare events in all three count modes:

- Up-count mode: used to generate an asymmetrical PWM waveform.
- Down-count mode: used to generate an asymmetrical PWM waveform.
- Up-down-count mode: used to generate a symmetrical PWM waveform.

To best illustrate the operation of the first three modes, the timing diagrams in [Figure 15-19](#) to [Figure 15-22](#) show when events are generated and how the EPWMxSYNCl signal interacts.

**Figure 15-19. Counter-Compare Event Waveforms in Up-Count Mode**

NOTE: An EPWMxSYNCl external synchronization event can cause a discontinuity in the TBCNT count sequence. This can lead to a compare event being skipped. This skipping is considered normal operation and must be taken into account.

**Figure 15-20. Counter-Compare Events in Down-Count Mode**

**Figure 15-21. Counter-Compare Events in Up-Down-Count Mode, TBCTL[PHSDIR = 0] Count Down on Synchronization Event**

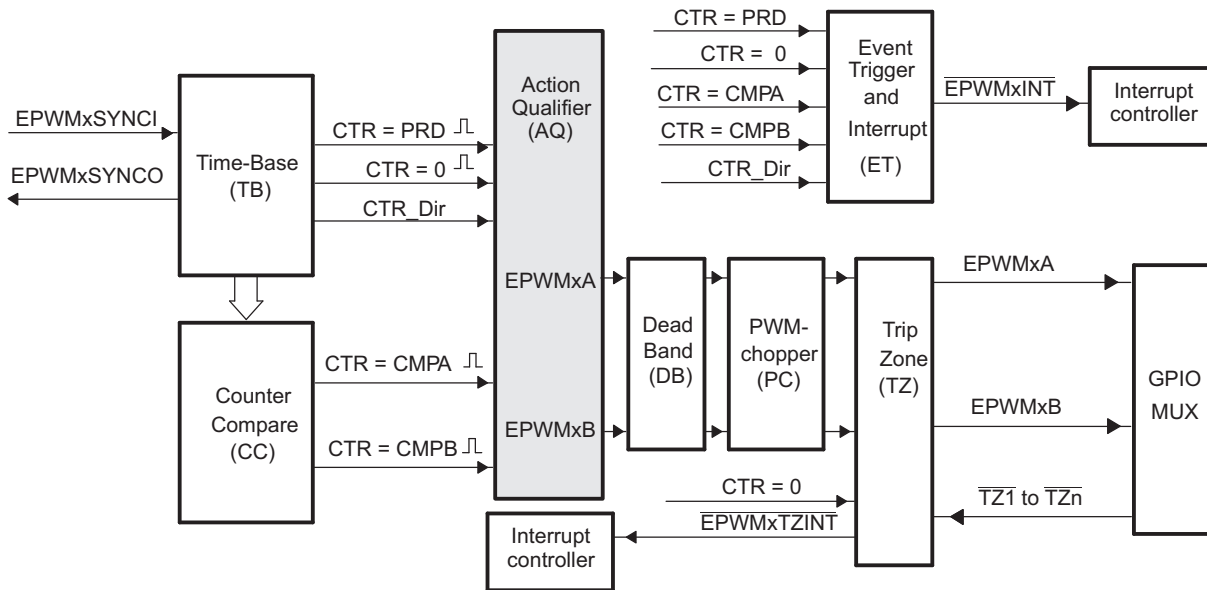

**Figure 15-22. Counter-Compare Events in Up-Down-Count Mode, TBCTL[PHSDIR = 1] Count Up on Synchronization Event**

### 15.2.2.5 Action-Qualifier (AQ) Submodule

Figure 15-23 shows the action-qualifier (AQ) submodule (see shaded block) in the ePWM system. The action-qualifier submodule has the most important role in waveform construction and PWM generation. It decides which events are converted into various action types, thereby producing the required switched waveforms at the EPWMxA and EPWMxB outputs.

**Figure 15-23. Action-Qualifier Submodule**

#### 15.2.2.5.1 Purpose of the Action-Qualifier Submodule

The action-qualifier submodule is responsible for the following:

- Qualifying and generating actions (set, clear, toggle) based on the following events:
  - CTR = PRD: Time-base counter equal to the period (TBCNT = TBPRD)
  - CTR = 0: Time-base counter equal to zero (TBCNT = 0000h)
  - CTR = CMPA: Time-base counter equal to the counter-compare A register (TBCNT = CMPA)
  - CTR = CMPB: Time-base counter equal to the counter-compare B register (TBCNT = CMPB)
- Managing priority when these events occur concurrently
- Providing independent control of events when the time-base counter is increasing and when it is decreasing.

#### 15.2.2.5.2 Controlling and Monitoring the Action-Qualifier Submodule

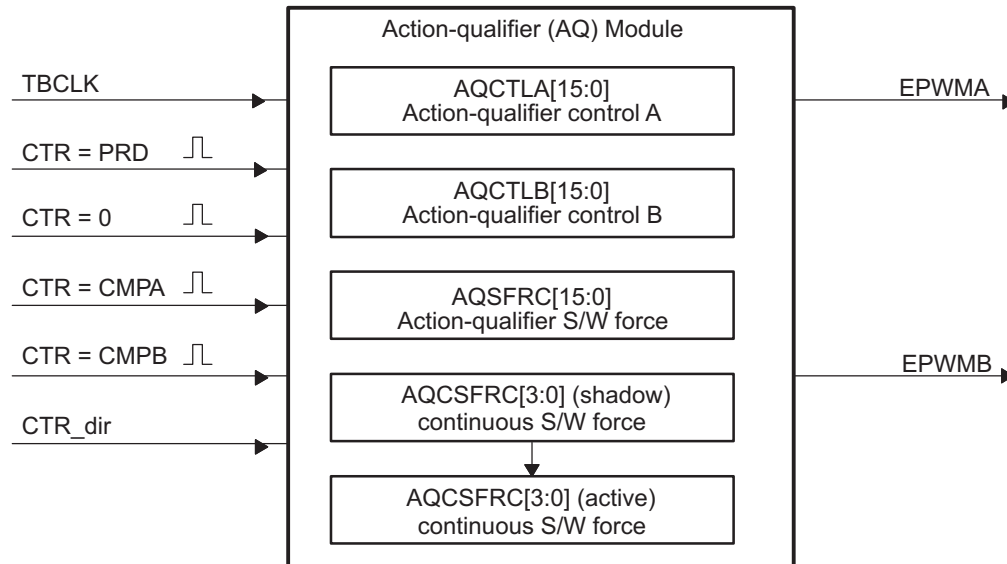

Table 15-15 lists the registers used to control and monitor the action-qualifier submodule.

**Table 15-15. Action-Qualifier Submodule Registers**

Acronym	Register Description	Address Offset	Shadowed
AQCTLA	Action-Qualifier Control Register For Output A (EPWMxA)	16h	No
AQCTLB	Action-Qualifier Control Register For Output B (EPWMxB)	18h	No
AQSFRC	Action-Qualifier Software Force Register	1Ah	No
AQCSFRC	Action-Qualifier Continuous Software Force	1Ch	Yes

The action-qualifier submodule is based on event-driven logic. It can be thought of as a programmable cross switch with events at the input and actions at the output, all of which are software controlled via the set of registers shown in Figure 15-24. The possible input events are summarized again in Table 15-16.

**Figure 15-24. Action-Qualifier Submodule Inputs and Outputs**

**Table 15-16. Action-Qualifier Submodule Possible Input Events**

Signal	Description	Registers Compared
CTR = PRD	Time-base counter equal to the period value	TBCNT = TBPRD
CTR = 0	Time-base counter equal to zero	TBCNT = 0000h
CTR = CMPA	Time-base counter equal to the counter-compare A	TBCNT = CMPA
CTR = CMPB	Time-base counter equal to the counter-compare B	TBCNT = CMPB
Software forced event	Asynchronous event initiated by software	

The software forced action is a useful asynchronous event. This control is handled by registers AQSFR and AQCSFR.

The action-qualifier submodule controls how the two outputs EPWMxA and EPWMxB behave when a particular event occurs. The event inputs to the action-qualifier submodule are further qualified by the counter direction (up or down). This allows for independent action on outputs on both the count-up and count-down phases.

The possible actions imposed on outputs EPWMxA and EPWMxB are:

- **Set High:** Set output EPWMxA or EPWMxB to a high level.
- **Clear Low:** Set output EPWMxA or EPWMxB to a low level.
- **Toggle:** If EPWMxA or EPWMxB is currently pulled high, then pull the output low. If EPWMxA or EPWMxB is currently pulled low, then pull the output high.
- **Do Nothing:** Keep outputs EPWMxA and EPWMxB at same level as currently set. Although the "Do Nothing" option prevents an event from causing an action on the EPWMxA and EPWMxB outputs, this event can still trigger interrupts. See the event-trigger submodule description in Section 15.2.2.9 for details.

Actions are specified independently for either output (EPWMxA or EPWMxB). Any or all events can be configured to generate actions on a given output. For example, both CTR = CMPA and CTR = CMPB can operate on output EPWMxA. All qualifier actions are configured via the control registers found at the end of this section.

For clarity, the drawings in this chapter use a set of symbolic actions. These symbols are summarized in [Figure 15-25](#). Each symbol represents an action as a marker in time. Some actions are fixed in time (zero and period) while the CMPA and CMPB actions are moveable and their time positions are programmed via the counter-compare A and B registers, respectively. To turn off or disable an action, use the "Do Nothing option"; it is the default at reset.

**Figure 15-25. Possible Action-Qualifier Actions for EPWMxA and EPWMxB Outputs**

S/W force	TB Counter equals:				Actions
	Zero	Comp A	Comp B	Period	
					Do Nothing
					Clear Low
					Set High
					Toggle

### 15.2.2.5.3 Action-Qualifier Event Priority

It is possible for the ePWM action qualifier to receive more than one event at the same time. In this case events are assigned a priority by the hardware. The general rule is events occurring later in time have a higher priority and software forced events always have the highest priority. The event priority levels for up-down-count mode are shown in [Table 15-17](#). A priority level of 1 is the highest priority and level 7 is the lowest. The priority changes slightly depending on the direction of TBCNT.

**Table 15-17. Action-Qualifier Event Priority for Up-Down-Count Mode**

Priority Level	Event if TBCNT is Incrementing TBCNT = 0 up to TBCNT = TBPRD	Event if TBCNT is Decrementing TBCNT = TBPRD down to TBCNT = 1
1 (Highest)	Software forced event	Software forced event
2	Counter equals CMPB on up-count (CBU)	Counter equals CMPB on down-count (CBD)
3	Counter equals CMPA on up-count (CAU)	Counter equals CMPA on down-count (CAD)
4	Counter equals zero	Counter equals period (TBPRD)
5	Counter equals CMPB on down-count (CBD) <sup>(1)</sup>	Counter equals CMPB on up-count (CBU) <sup>(1)</sup>
6 (Lowest)	Counter equals CMPA on down-count (CAD) <sup>(1)</sup>	Counter equals CMPA on up-count (CBU) <sup>(1)</sup>

<sup>(1)</sup> To maintain symmetry for up-down-count mode, both up-events (CAU/CBU) and down-events (CAD/CBD) can be generated for TBPRD. Otherwise, up-events can occur only when the counter is incrementing and down-events can occur only when the counter is decrementing.

[Table 15-18](#) shows the action-qualifier priority for up-count mode. In this case, the counter direction is always defined as up and thus down-count events will never be taken.

**Table 15-18. Action-Qualifier Event Priority for Up-Count Mode**

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to period (TBPRD)
3	Counter equal to CMPB on up-count (CBU)
4	Counter equal to CMPA on up-count (CAU)
5 (Lowest)	Counter equal to Zero

[Table 15-19](#) shows the action-qualifier priority for down-count mode. In this case, the counter direction is always defined as down and thus up-count events will never be taken.

**Table 15-19. Action-Qualifier Event Priority for Down-Count Mode**

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to Zero
3	Counter equal to CMPB on down-count (CBD)
4	Counter equal to CMPA on down-count (CAD)
5 (Lowest)	Counter equal to period (TBPRD)

It is possible to set the compare value greater than the period. In this case the action will take place as shown in [Table 15-20](#).

**Table 15-20. Behavior if CMPA/CMPB is Greater than the Period**

Counter Mode	Compare on Up-Count Event CAU/CBU	Compare on Down-Count Event CAU/CBU
Up-Count Mode	If $CMPA/CMPB \leq TBPRD$ period, then the event occurs on a compare match ( $TBCNT = CMPA$ or $CMPB$ ). If $CMPA/CMPB > TBPRD$ , then the event will not occur.	Never occurs.
Down-Count Mode	Never occurs.	If $CMPA/CMPB < TBPRD$ , the event will occur on a compare match ( $TBCNT = CMPA$ or $CMPB$ ). If $CMPA/CMPB \geq TBPRD$ , the event will occur on a period match ( $TBCNT = TBPRD$ ).
Up-Down-Count Mode	If $CMPA/CMPB < TBPRD$ and the counter is incrementing, the event occurs on a compare match ( $TBCNT = CMPA$ or $CMPB$ ). If $CMPA/CMPB \geq TBPRD$ , the event will occur on a period match ( $TBCNT = TBPRD$ ).	If $CMPA/CMPB < TBPRD$ and the counter is decrementing, the event occurs on a compare match ( $TBCNT = CMPA$ or $CMPB$ ). If $CMPA/CMPB \geq TBPRD$ , the event occurs on a period match ( $TBCNT = TBPRD$ ).

#### 15.2.2.5.4 Waveforms for Common Configurations

**NOTE:** The waveforms in this chapter show the ePWMs behavior for a static compare register value. In a running system, the active compare registers (CMPA and CMPB) are typically updated from their respective shadow registers once every period. The user specifies when the update will take place; either when the time-base counter reaches zero or when the time-base counter reaches period. There are some cases when the action based on the new value can be delayed by one period or the action based on the old value can take effect for an extra period. Some PWM configurations avoid this situation. These include, but are not limited to, the following:

**Use up-down-count mode to generate a symmetric PWM:**

- If you load CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1.
- If you load CMPA/CMPB on period, then use CMPA/CMPB values less than or equal to  $TBPRD - 1$ .

This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

**Use up-down-count mode to generate an asymmetric PWM:**

- To achieve 50%-0% asymmetric PWM use the following configuration: Load CMPA/CMPB on period and use the period action to clear the PWM and a compare-up action to set the PWM. Modulate the compare value from 0 to TBPRD to achieve 50%-0% PWM duty.

**When using up-count mode to generate an asymmetric PWM:**

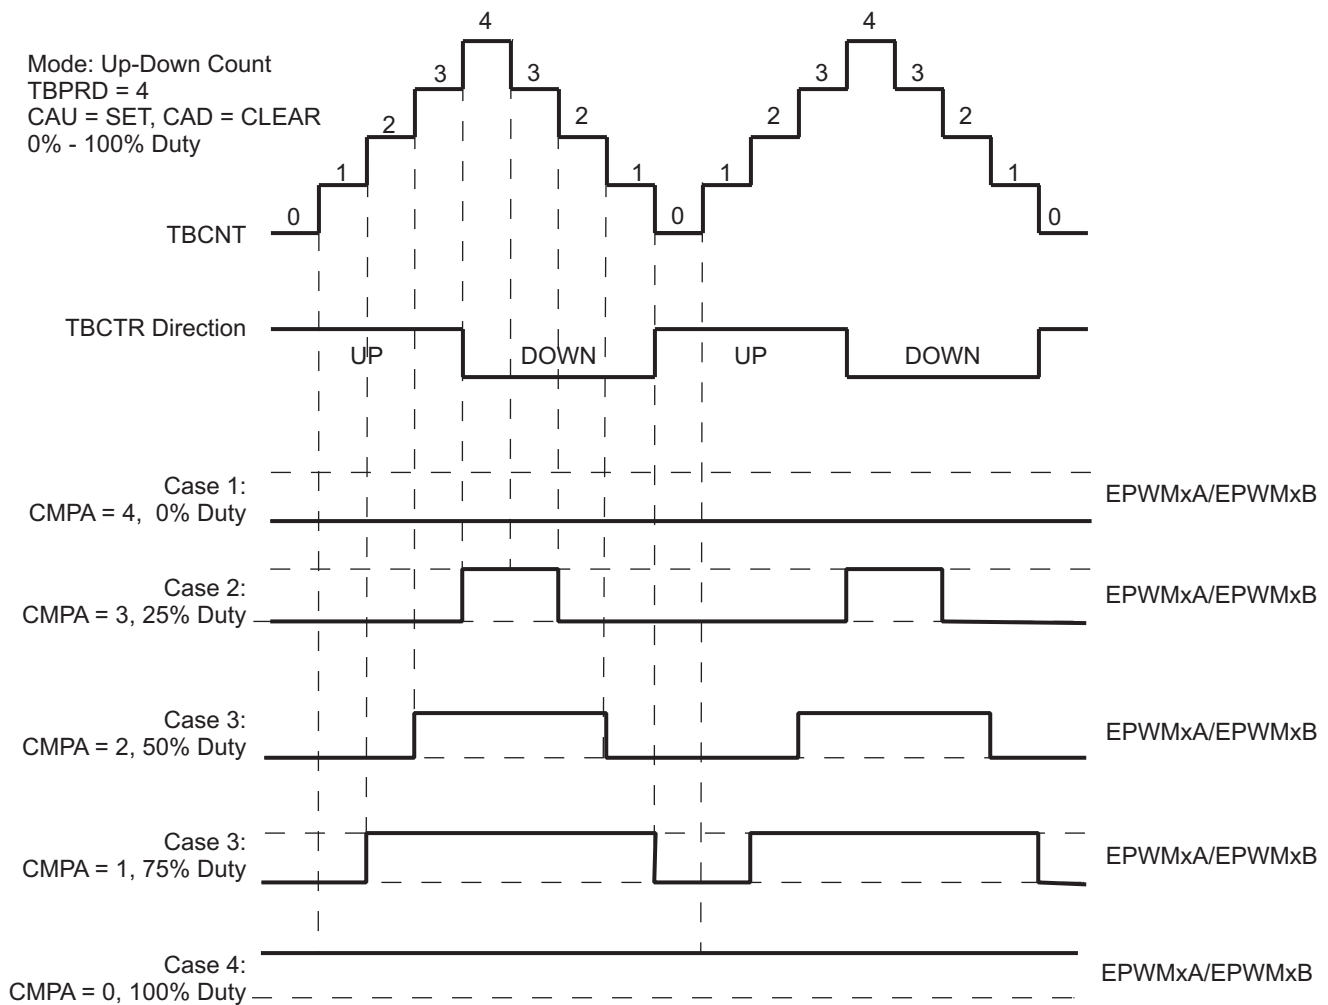

- To achieve 0-100% asymmetric PWM use the following configuration: Load CMPA/CMPB on TBPRD. Use the Zero action to set the PWM and a compare-up action to clear the PWM. Modulate the compare value from 0 to  $TBPRD+1$  to achieve 0-100% PWM duty.

Figure 15-26 shows how a symmetric PWM waveform can be generated using the up-down-count mode of the TBCNT. In this mode 0%-100% DC modulation is achieved by using equal compare matches on the up count and down count portions of the waveform. In the example shown, CMPA is used to make the comparison. When the counter is incrementing the CMPA match will pull the PWM output high. Likewise, when the counter is decrementing the compare match will pull the PWM signal low. When  $CMPA = 0$ , the PWM signal is low for the entire period giving the 0% duty waveform. When  $CMPA = TBPRD$ , the PWM signal is high achieving 100% duty.

When using this configuration in practice, if you load  $CMPA/CMPB$  on zero, then use  $CMPA/CMPB$  values greater than or equal to 1. If you load  $CMPA/CMPB$  on period, then use  $CMPA/CMPB$  values less than or equal to  $TBPRD-1$ . This means there will always be a pulse of at least one  $TBCLK$  cycle in a PWM period which, when very short, tend to be ignored by the system.

Figure 15-26. Up-Down-Count Mode Symmetrical Waveform

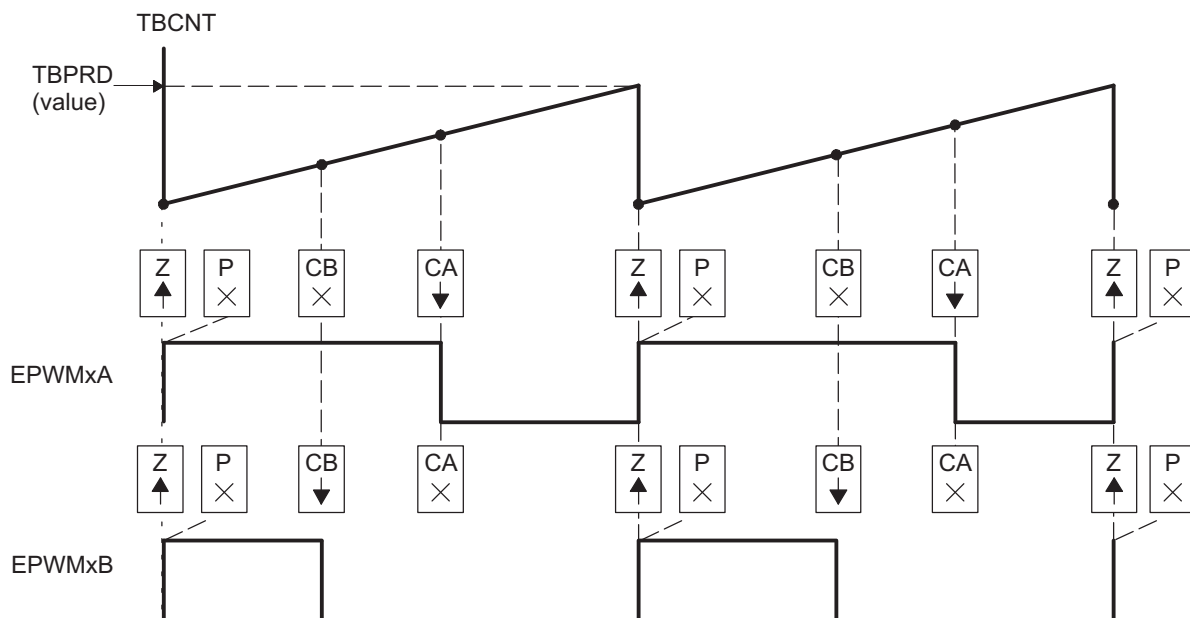

The PWM waveforms in [Figure 15-27](#) through [Figure 15-32](#) show some common action-qualifier configurations. Some conventions used in the figures are as follows:

- TBCNT, CMPA, and CMPB refer to the value written in their respective registers. The active register, not the shadow register, is used by the hardware.
- CMPx, refers to either CMPA or CMPB.
- EPWMxA and EPWMxB refer to the output signals from ePWMx
- Up-Down means Count-up-and-down mode, Up means up-count mode and Dwn means down-count mode
- Sym = Symmetric, Asym = Asymmetric

[Table 15-21](#) and [Table 15-22](#) contains initialization and runtime register configurations for the waveforms in [Figure 15-27](#).

**Figure 15-27. Up, Single Edge Asymmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB—Active High**

- (1)  $PWM\ period = (TBPRD + 1) \times T_{TBCLK}$
- (2) Duty modulation for EPWMxA is set by CMPA, and is active high (that is, high time duty proportional to CMPA).
- (3) Duty modulation for EPWMxB is set by CMPB and is active high (that is, high time duty proportional to CMPB).
- (4) The "Do Nothing" actions ( X ) are shown for completeness, but will not be shown on subsequent diagrams.
- (5) Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCNT wraps from period to 0000h.

### 15.2.2.6 Dead-Band Generator (DB) Submodule

Figure 15-33 illustrates the dead-band generator submodule within the ePWM module.

**Figure 15-33. Dead-Band Generator Submodule**

#### 15.2.2.6.1 Purpose of the Dead-Band Submodule

The "Action-qualifier (AQ) Module" section discussed how it is possible to generate the required dead-band by having full control over edge placement using both the CMPA and CMPB resources of the ePWM module. However, if the more classical edge delay-based dead-band with polarity control is required, then the dead-band generator submodule should be used.

The key functions of the dead-band generator submodule are:

- Generating appropriate signal pairs (EPWMxA and EPWMxB) with dead-band relationship from a single EPWMxA input
- Programming signal pairs for:
  - Active high (AH)
  - Active low (AL)
  - Active high complementary (AHC)
  - Active low complementary (ALC)
- Adding programmable delay to rising edges (RED)
- Adding programmable delay to falling edges (FED)
- Can be totally bypassed from the signal path (note dotted lines in diagram)

#### 15.2.2.6.2 Controlling and Monitoring the Dead-Band Submodule

The dead-band generator submodule operation is controlled and monitored via the following registers:

**Table 15-33. Dead-Band Generator Submodule Registers**

Acronym	Register Description	Address Offset	Shadowed
DBCTL	Dead-Band Control Register	1Eh	No
DBRED	Dead-Band Rising Edge Delay Count Register	20h	No
DBFED	Dead-Band Falling Edge Delay Count Register	22h	No

### 15.2.2.6.3 Operational Highlights for the Dead-Band Generator Submodule

The following sections provide the operational highlights.

The dead-band submodule has two groups of independent selection options as shown in Figure 15-34.

- Input Source Selection:** The input signals to the dead-band module are the EPWMxA and EPWMxB output signals from the action-qualifier. In this section they will be referred to as EPWMxA In and EPWMxB In. Using the DBCTL[IN\_MODE] control bits, the signal source for each delay, falling-edge or rising-edge, can be selected:
  - EPWMxA In is the source for both falling-edge and rising-edge delay. This is the default mode.
  - EPWMxA In is the source for falling-edge delay, EPWMxB In is the source for rising-edge delay.
  - EPWMxA In is the source for rising edge delay, EPWMxB In is the source for falling-edge delay.
  - EPWMxB In is the source for both falling-edge and rising-edge delay.
- Output Mode Control:** The output mode is configured by way of the DBCTL[OUT\_MODE] bits. These bits determine if the falling-edge delay, rising-edge delay, neither, or both are applied to the input signals.
- Polarity Control:** The polarity control (DBCTL[POLSEL]) allows you to specify whether the rising-edge delayed signal and/or the falling-edge delayed signal is to be inverted before being sent out of the dead-band submodule.

Figure 15-34. Configuration Options for the Dead-Band Generator Submodule

Although all combinations are supported, not all are typical usage modes. [Table 15-34](#) lists some classical dead-band configurations. These modes assume that the DBCTL[IN\_MODE] is configured such that EPWMxA In is the source for both falling-edge and rising-edge delay. Enhanced, or non-traditional modes can be achieved by changing the input signal source. The modes shown in [Table 15-34](#) fall into the following categories:

- **Mode 1: Bypass both falling-edge delay (FED) and rising-edge delay (RED)** Allows you to fully disable the dead-band submodule from the PWM signal path.
- **Mode 2-5: Classical Dead-Band Polarity Settings** These represent typical polarity configurations that should address all the active high/low modes required by available industry power switch gate drivers. The waveforms for these typical cases are shown in [Figure 15-35](#). Note that to generate equivalent waveforms to [Figure 15-35](#), configure the action-qualifier submodule to generate the signal as shown for EPWMxA.
- **Mode 6: Bypass rising-edge-delay and Mode 7: Bypass falling-edge-delay** Finally the last two entries in [Table 15-34](#) show combinations where either the falling-edge-delay (FED) or rising-edge-delay (RED) blocks are bypassed.

**Table 15-34. Classical Dead-Band Operating Modes**

Mode	Mode Description <sup>(1)</sup>	DBCTL[POLSEL]		DBCTL[OUT_MODE]	
		S3	S2	S1	S0
1	EPWMxA and EPWMxB Passed Through (No Delay)	x	x	0	0
2	Active High Complementary (AHC)	1	0	1	1
3	Active Low Complementary (ALC)	0	1	1	1
4	Active High (AH)	0	0	1	1
5	Active Low (AL)	1	1	1	1
6	EPWMxA Out = EPWMxA In (No Delay) EPWMxB Out = EPWMxA In with Falling Edge Delay	0 or 1	0 or 1	0	1
7	EPWMxA Out = EPWMxA In with Rising Edge Delay EPWMxB Out = EPWMxB In with No Delay	0 or 1	0 or 1	1	0

<sup>(1)</sup> These are classical dead-band modes and assume that DBCTL[IN\_MODE] = 0,0. That is, EPWMxA in is the source for both the falling-edge and rising-edge delays. Enhanced, non-traditional modes can be achieved by changing the IN\_MODE configuration.

Figure 15-35 shows waveforms for typical cases where 0% < duty < 100%.

**Figure 15-35. Dead-Band Waveforms for Typical Cases (0% < Duty < 100%)**

The dead-band submodule supports independent values for rising-edge (RED) and falling-edge (FED) delays. The amount of delay is programmed using the DBRED and DBFED registers. These are 10-bit registers and their value represents the number of time-base clock, TBCLK, periods a signal edge is delayed by. For example, the formula to calculate falling-edge-delay and rising-edge-delay are:

$$FED = DBFED \times T_{TBCLK}$$

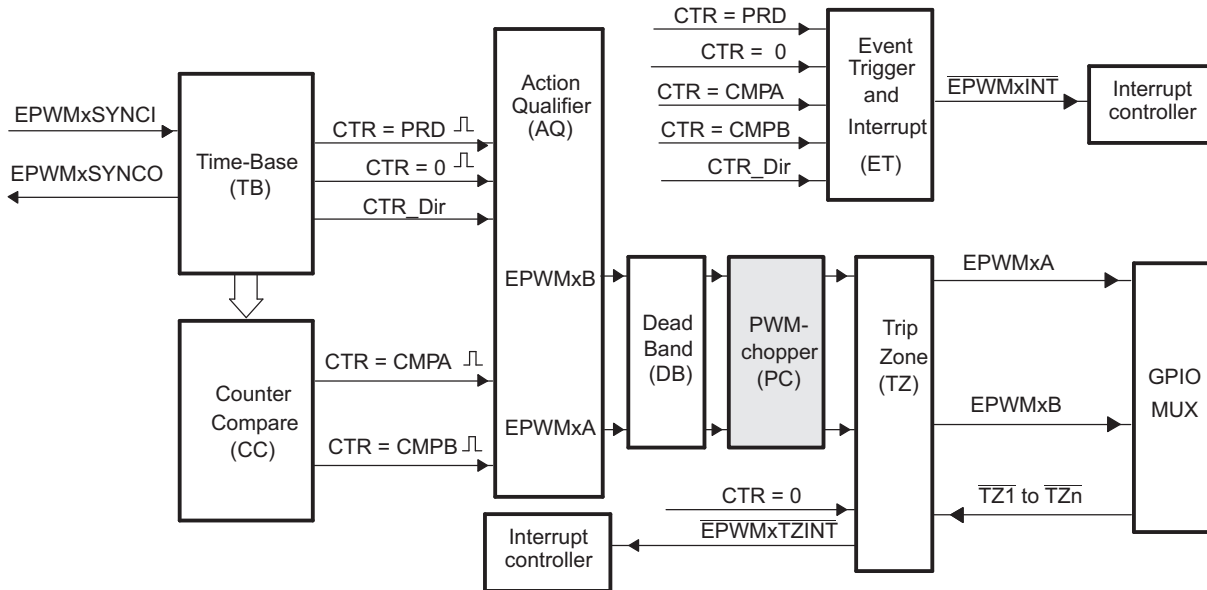

$$RED = DBRED \times T_{TBCLK}$$

Where  $T_{TBCLK}$  is the period of TBCLK, the prescaled version of SYSCLKOUT.

### 15.2.2.7 PWM-Chopper (PC) Submodule

Figure 15-36 illustrates the PWM-chopper (PC) submodule within the ePWM module. The PWM-chopper submodule allows a high-frequency carrier signal to modulate the PWM waveform generated by the action-qualifier and dead-band submodules. This capability is important if you need pulse transformer-based gate drivers to control the power switching elements.

**Figure 15-36. PWM-Chopper Submodule**

#### 15.2.2.7.1 Purpose of the PWM-Chopper Submodule

The key functions of the PWM-chopper submodule are:

- Programmable chopping (carrier) frequency
- Programmable pulse width of first pulse
- Programmable duty cycle of second and subsequent pulses
- Can be fully bypassed if not required

#### 15.2.2.7.2 Controlling the PWM-Chopper Submodule

The PWM-chopper submodule operation is controlled via the register in [Table 15-35](#).

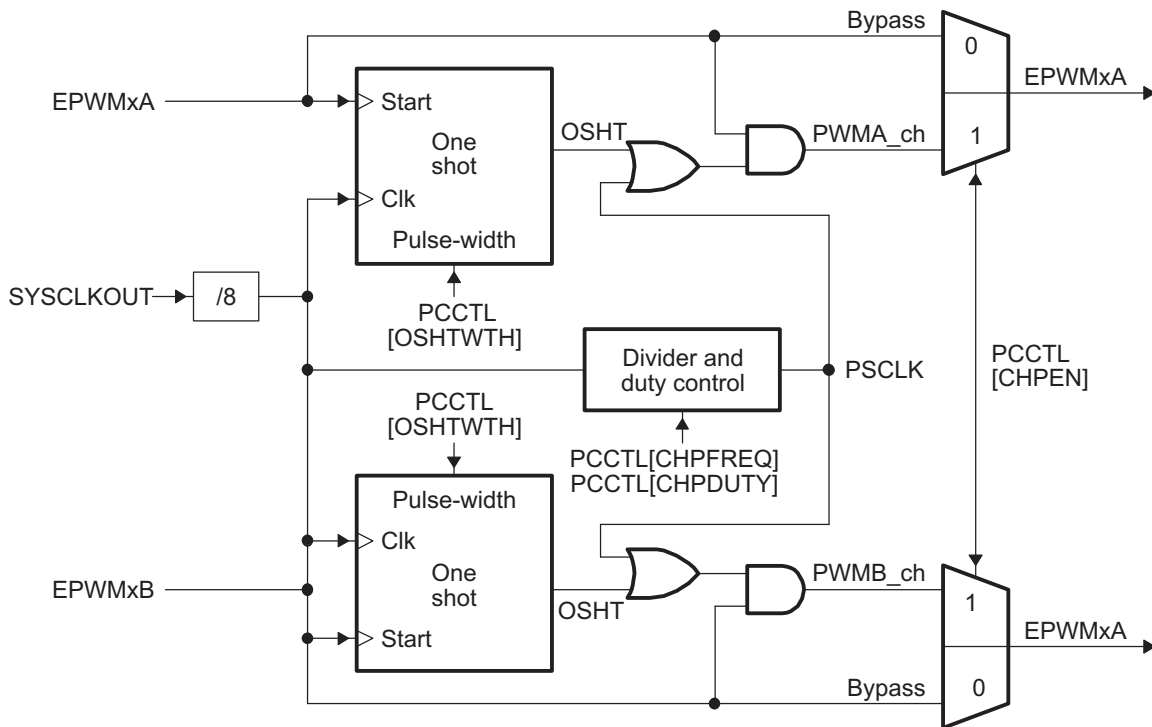

**Table 15-35. PWM-Chopper Submodule Registers**

Acronym	Register Description	Address Offset	Shadowed
PCCTL	PWM-chopper Control Register	3Ch	No

15.2.2.7.3 Operational Highlights for the PWM-Chopper Submodule

Figure 15-37 shows the operational details of the PWM-chopper submodule. The carrier clock is derived from SYSCLKOUT. Its frequency and duty cycle are controlled via the CHPFREQ and CHPDUTY bits in the PCCTL register. The one-shot block is a feature that provides a high energy first pulse to ensure hard and fast power switch turn on, while the subsequent pulses sustain pulses, ensuring the power switch remains on. The one-shot width is programmed via the OSHTWTH bits. The PWM-chopper submodule can be fully disabled (bypassed) via the CHPEN bit.

Figure 15-37. PWM-Chopper Submodule Signals and Registers

### 15.2.2.7.4 Waveforms

Figure 15-38 shows simplified waveforms of the chopping action only; one-shot and duty-cycle control are not shown. Details of the one-shot and duty-cycle control are discussed in the following sections.

**Figure 15-38. Simple PWM-Chopper Submodule Waveforms Showing Chopping Action Only**

#### 15.2.2.7.4.1 One-Shot Pulse

The width of the first pulse can be programmed to any of 16 possible pulse width values. The width or period of the first pulse is given by:

$$T_{1stpulse} = T_{SYSCLKOUT} \times 8 \times OSHTWTH$$

Where  $T_{SYSCLKOUT}$  is the period of the system clock (SYSCLKOUT) and OSHTWTH is the four control bits (value from 1 to 16)

Figure 15-39 shows the first and subsequent sustaining pulses.

**Figure 15-39. PWM-Chopper Submodule Waveforms Showing the First Pulse and Subsequent Sustaining Pulses**

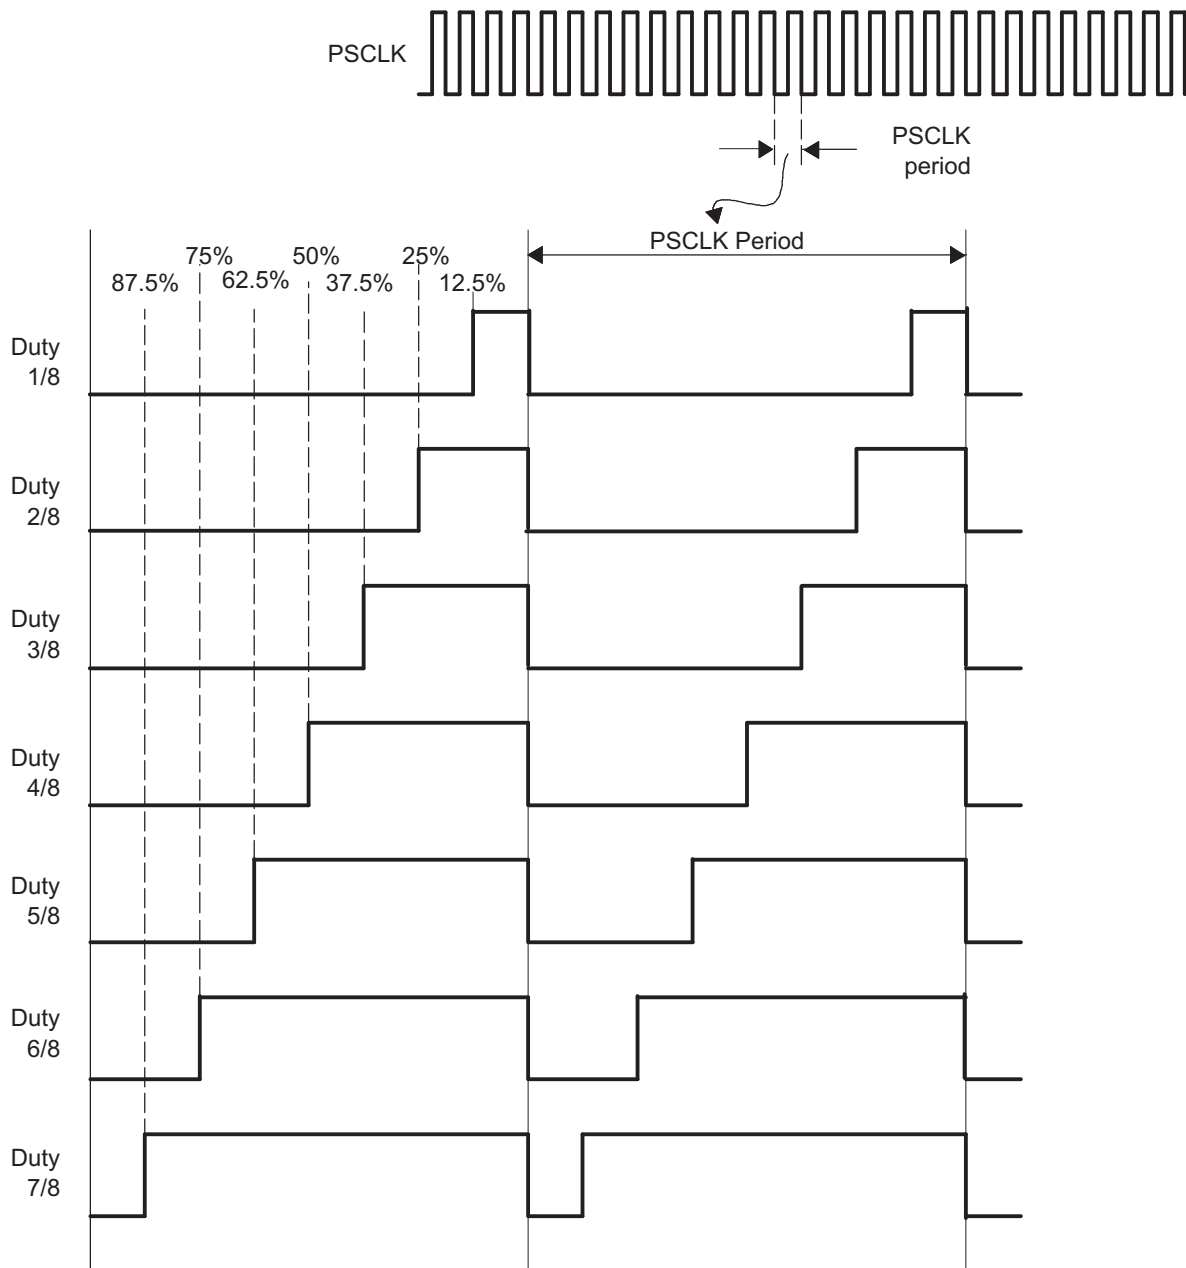

**15.2.2.7.4.2 Duty Cycle Control**

Pulse transformer-based gate drive designs need to comprehend the magnetic properties or characteristics of the transformer and associated circuitry. Saturation is one such consideration. To assist the gate drive designer, the duty cycles of the second and subsequent pulses have been made programmable. These sustaining pulses ensure the correct drive strength and polarity is maintained on the power switch gate during the on period, and hence a programmable duty cycle allows a design to be tuned or optimized via software control.

Figure 15-40 shows the duty cycle control that is possible by programming the CHPDUTY bits. One of seven possible duty ratios can be selected ranging from 12.5% to 87.5%.

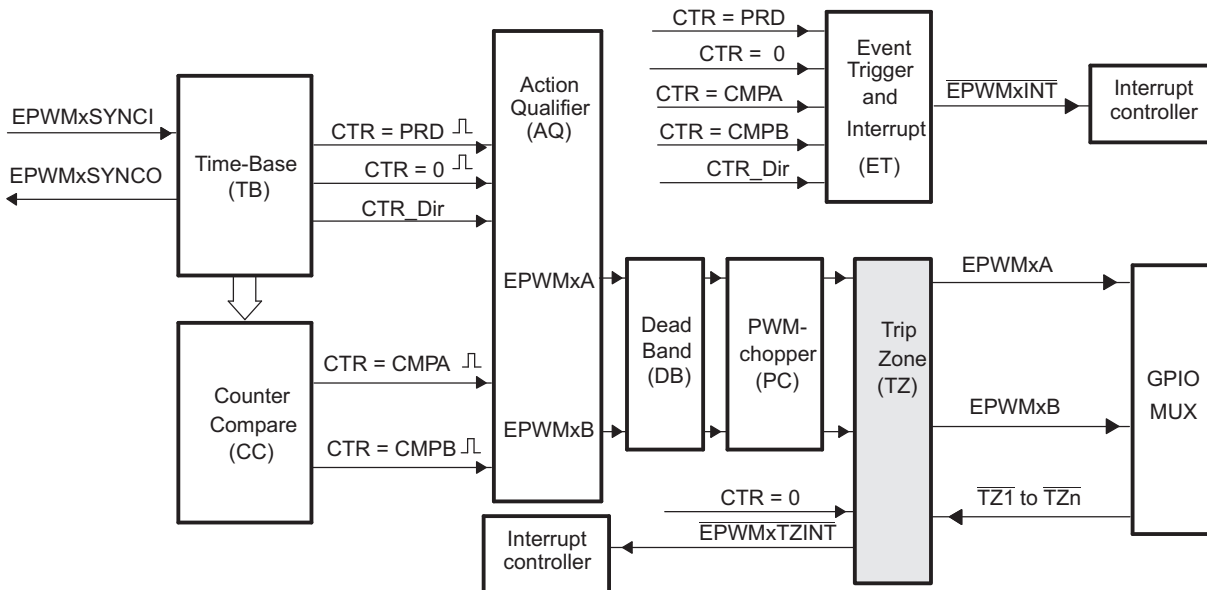

**Figure 15-40. PWM-Chopper Submodule Waveforms Showing the Pulse Width (Duty Cycle) Control of Sustaining Pulses**

### 15.2.2.8 Trip-Zone (TZ) Submodule

Figure 15-41 shows how the trip-zone (TZ) submodule fits within the ePWM module. Each ePWM module is connected to every  $\overline{TZ}$  signal that are sourced from the GPIO MUX. These signals indicates external fault or trip conditions, and the ePWM outputs can be programmed to respond accordingly when faults occur. See Section 15.1.2 to determine the number of trip-zone pins available for the device.

**Figure 15-41. Trip-Zone Submodule**

#### 15.2.2.8.1 Purpose of the Trip-Zone Submodule

The key functions of the trip-zone submodule are:

- Trip inputs  $\overline{TZ1}$  to  $\overline{TZn}$  can be flexibly mapped to any ePWM module.
- Upon a fault condition, outputs  $EPWMxA$  and  $EPWMxB$  can be forced to one of the following:
  - High
  - Low
  - High-impedance
  - No action taken
- Support for one-shot trip (OSHT) for major short circuits or over-current conditions.
- Support for cycle-by-cycle tripping (CBC) for current limiting operation.
- Each trip-zone input pin can be allocated to either one-shot or cycle-by-cycle operation.
- Interrupt generation is possible on any trip-zone pin.
- Software-forced tripping is also supported.
- The trip-zone submodule can be fully bypassed if it is not required.

### 15.2.2.8.2 Controlling and Monitoring the Trip-Zone Submodule

The trip-zone submodule operation is controlled and monitored through the following registers:

**Table 15-36. Trip-Zone Submodule Registers**

Acronym	Register Description	Address Offset	Shadowed
TZSEL	Trip-Zone Select Register	24h	No
TZCTL	Trip-Zone Control Register	28h	No
TZEINT	Trip-Zone Enable Interrupt Register	2Ah	No
TZFLG	Trip-Zone Flag Register	2Ch	No
TZCLR	Trip-Zone Clear Register	2Eh	No
TZFRC	Trip-Zone Force Register	30h	No

### 15.2.2.8.3 Operational Highlights for the Trip-Zone Submodule

The following sections describe the operational highlights and configuration options for the trip-zone submodule.

The trip-zone signals at pin  $\overline{TZ1}$  to  $\overline{TZn}$  is an active-low input signal. When the pin goes low, it indicates that a trip event has occurred. Each ePWM module can be individually configured to ignore or use each of the trip-zone pins. Which trip-zone pins are used by a particular ePWM module is determined by the TZSEL register for that specific ePWM module. The trip-zone signal may or may not be synchronized to the system clock (SYSCLKOUT). A minimum of 1 SYSCLKOUT low pulse on the  $\overline{TZn}$  inputs is sufficient to trigger a fault condition in the ePWM module. The asynchronous trip makes sure that if clocks are missing for any reason, the outputs can still be tripped by a valid event present on the  $\overline{TZn}$  inputs.

The  $\overline{TZn}$  input can be individually configured to provide either a cycle-by-cycle or one-shot trip event for a ePWM module. The configuration is determined by the TZSEL[CBCn] and TZSEL[OSHTn] bits (where n corresponds to the trip pin) respectively.

- Cycle-by-Cycle (CBC):** When a cycle-by-cycle trip event occurs, the action specified in the TZCTL register is carried out immediately on the EPWMxA and/or EPWMxB output. [Table 15-37](#) lists the possible actions. In addition, the cycle-by-cycle trip event flag (TZFLG[CBC]) is set and a EPWMxTZINT interrupt is generated if it is enabled in the TZEINT register.
 

The specified condition on the pins is automatically cleared when the ePWM time-base counter reaches zero (TBCNT = 0000h) if the trip event is no longer present. Therefore, in this mode, the trip event is cleared or reset every PWM cycle. The TZFLG[CBC] flag bit will remain set until it is manually cleared by writing to the TZCLR[CBC] bit. If the cycle-by-cycle trip event is still present when the TZFLG[CBC] bit is cleared, then it will again be immediately set.
- One-Shot (OSHT):** When a one-shot trip event occurs, the action specified in the TZCTL register is carried out immediately on the EPWMxA and/or EPWMxB output. [Table 15-37](#) lists the possible actions. In addition, the one-shot trip event flag (TZFLG[OST]) is set and a EPWMxTZINT interrupt is generated if it is enabled in the TZEINT register. The one-shot trip condition must be cleared manually by writing to the TZCLR[OST] bit.

The action taken when a trip event occurs can be configured individually for each of the ePWM output pins by way of the TZCTL[TZA] and TZCTL[TZB] register bits. One of four possible actions, shown in [Table 15-37](#), can be taken on a trip event.

**Table 15-37. Possible Actions On a Trip Event**

TZCTL[TZA] and/or TZCTL[TZB]	EPWMxA and/or EPWMxB	Comment
0	High-Impedance	Tripped
1h	Force to High State	Tripped
2h	Force to Low State	Tripped
3h	No Change	Do Nothing. No change is made to the output.

**Example 15-2. Trip-Zone Configurations**
**Scenario A:**

A one-shot trip event on  $\overline{TZ1}$  pulls both EPWM1A, EPWM1B low and also forces EPWM2A and EPWM2B high.

- Configure the ePWM1 registers as follows:
  - TZSEL[OSHT1] = 1: enables  $\overline{TZ}$  as a one-shot event source for ePWM1
  - TZCTL[TZA] = 2: EPWM1A will be forced low on a trip event.
  - TZCTL[TZB] = 2: EPWM1B will be forced low on a trip event.
- Configure the ePWM2 registers as follows:
  - TZSEL[OSHT1] = 1: enables  $\overline{TZ}$  as a one-shot event source for ePWM2
  - TZCTL[TZA] = 1: EPWM2A will be forced high on a trip event.
  - TZCTL[TZB] = 1: EPWM2B will be forced high on a trip event.

**Scenario B:**

A cycle-by-cycle event on  $\overline{TZ5}$  pulls both EPWM1A, EPWM1B low.

A one-shot event on  $\overline{TZ1}$  or  $\overline{TZ6}$  puts EPWM2A into a high impedance state.

- Configure the ePWM1 registers as follows:
  - TZSEL[CBC5] = 1: enables  $\overline{TZ5}$  as a one-shot event source for ePWM1
  - TZCTL[TZA] = 2: EPWM1A will be forced low on a trip event.
  - TZCTL[TZB] = 2: EPWM1B will be forced low on a trip event.
- Configure the ePWM2 registers as follows:
  - TZSEL[OSHT1] = 1: enables  $\overline{TZ1}$  as a one-shot event source for ePWM2
  - TZSEL[OSHT6] = 1: enables  $\overline{TZ6}$  as a one-shot event source for ePWM1
  - TZCTL[TZA] = 0: EPWM1A will be put into a high-impedance state on a trip event.
  - TZCTL[TZB] = 3: EPWM1B will ignore the trip event.

**15.2.2.8.4 Generating Trip Event Interrupts**

Figure 15-42 and Figure 15-43 illustrate the trip-zone submodule control and interrupt logic, respectively.

Figure 15-42. Trip-Zone Submodule Mode Control Logic

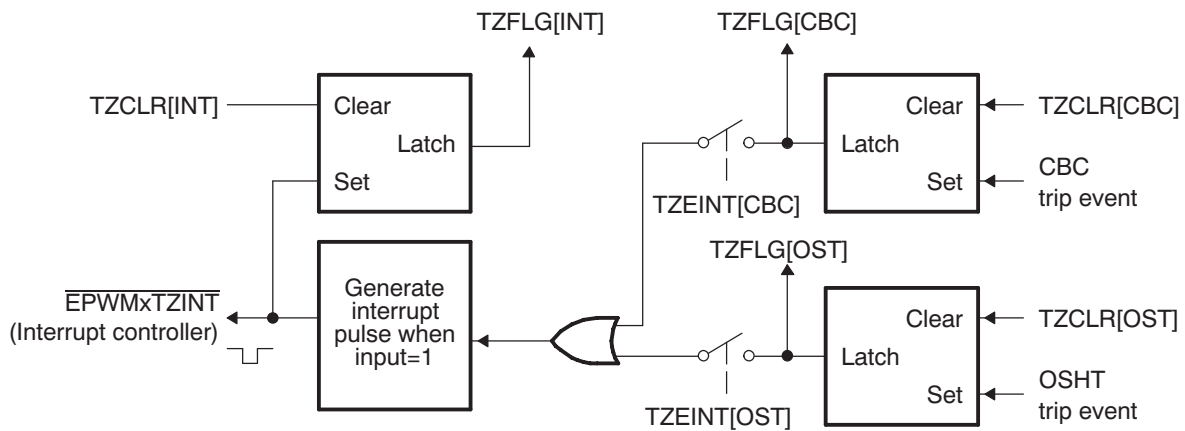

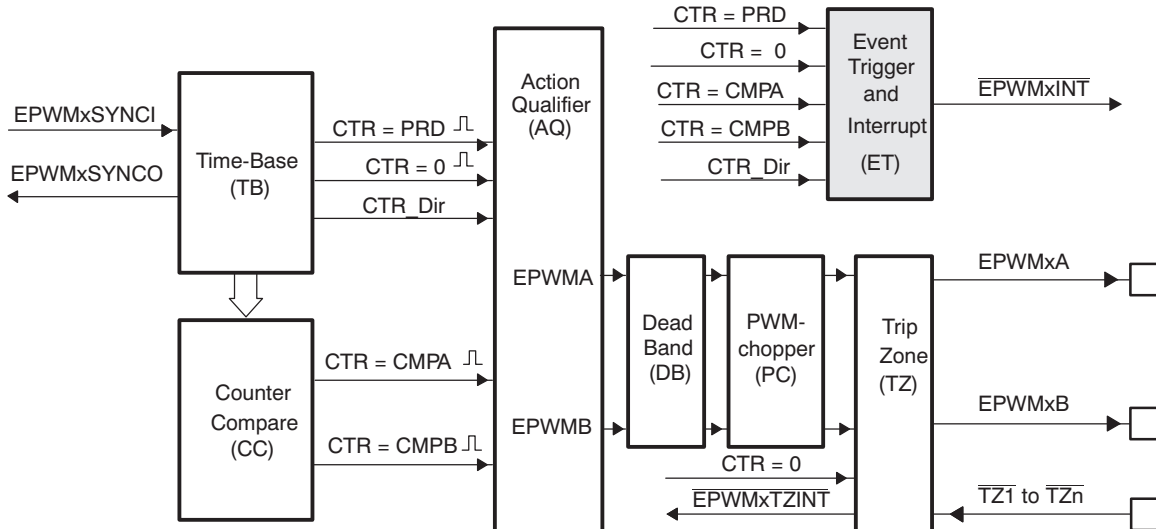

Figure 15-43. Trip-Zone Submodule Interrupt Logic

### 15.2.2.9 Event-Trigger (ET) Submodule

Figure 15-44 shows the event-trigger (ET) submodule in the ePWM system. The event-trigger submodule manages the events generated by the time-base submodule and the counter-compare submodule to generate an interrupt to the CPU.

**Figure 15-44. Event-Trigger Submodule**

#### 15.2.2.9.1 Purpose of the Event-Trigger Submodule

The key functions of the event-trigger submodule are:

- Receives event inputs generated by the time-base and counter-compare submodules
- Uses the time-base direction information for up/down event qualification
- Uses prescaling logic to issue interrupt requests at:
  - Every event
  - Every second event
  - Every third event
- Provides full visibility of event generation via event counters and flags

#### 15.2.2.9.2 Controlling and Monitoring the Event-Trigger Submodule

The key registers used to configure the event-trigger submodule are shown in Table 15-38:

**Table 15-38. Event-Trigger Submodule Registers**

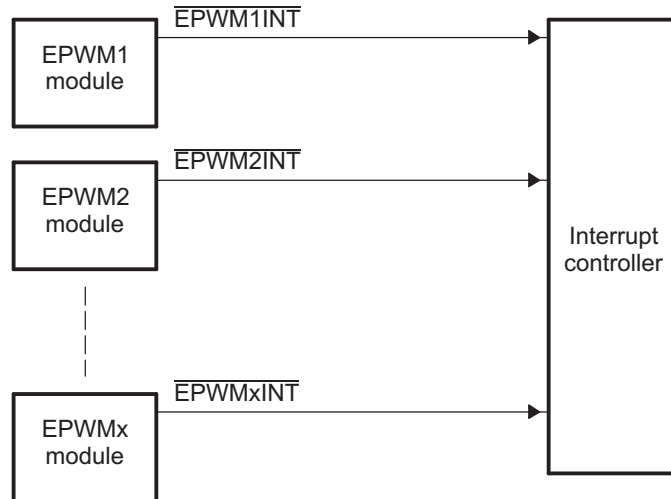

Acronym	Register Description	Address Offset	Shadowed
ETSEL	Event-Trigger Selection Register	32h	No
ETPS	Event-Trigger Prescale Register	34h	No
ETFLG	Event-Trigger Flag Register	36h	No
ETCLR	Event-Trigger Clear Register	38h	No
ETFRFC	Event-Trigger Force Register	3Ah	No

15.2.2.9.3 Operational Overview of the Event-Trigger Submodule

The following sections describe the event-trigger submodule's operational highlights.

Each ePWM module has one interrupt request line connected to the interrupt controller as shown in Figure 15-45.

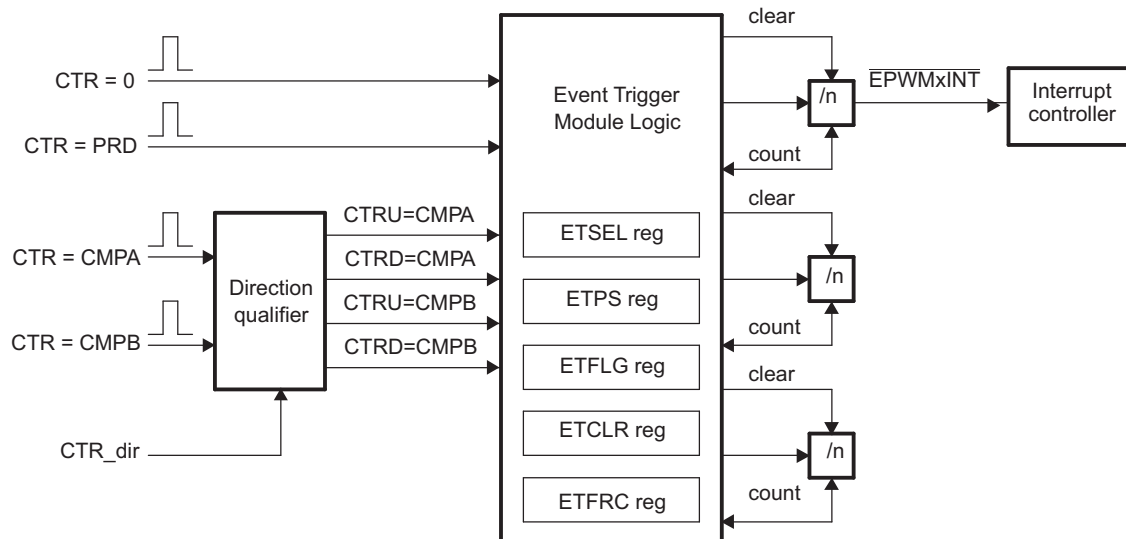

Figure 15-45. Event-Trigger Submodule Inter-Connectivity to Interrupt Controller

The event-trigger submodule monitors various event conditions (the left side inputs to event-trigger submodule shown in Figure 15-46) and can be configured to prescale these events before issuing an Interrupt request. The event-trigger prescaling logic can issue Interrupt requests at:

- Every event
- Every second event
- Every third event

Figure 15-46. Event-Trigger Submodule Showing Event Inputs and Prescaled Outputs

- ETSEL—This selects which of the possible events will trigger an interrupt.
- ETPS—This programs the event prescaling options previously mentioned.
- ETFLG—These are flag bits indicating status of the selected and prescaled events.
- ETCLR—These bits allow you to clear the flag bits in the ETFLG register via software.
- ETFRC—These bits allow software forcing of an event. Useful for debugging or software intervention.

A more detailed look at how the various register bits interact with the Interrupt is shown in [Figure 15-47](#).

[Figure 15-47](#) shows the event-trigger's interrupt generation logic. The interrupt-period (ETPS[INTPRD]) bits specify the number of events required to cause an interrupt pulse to be generated. The choices available are:

- Do not generate an interrupt
- Generate an interrupt on every event
- Generate an interrupt on every second event
- Generate an interrupt on every third event

An interrupt cannot be generated on every fourth or more events.

Which event can cause an interrupt is configured by the interrupt selection (ETSEL[INTSEL]) bits. The event can be one of the following:

- Time-base counter equal to zero (TBCNT = 0000h).
- Time-base counter equal to period (TBCNT = TBPRD).
- Time-base counter equal to the compare A register (CMPA) when the timer is incrementing.
- Time-base counter equal to the compare A register (CMPA) when the timer is decrementing.
- Time-base counter equal to the compare B register (CMPB) when the timer is incrementing.
- Time-base counter equal to the compare B register (CMPB) when the timer is decrementing.

The number of events that have occurred can be read from the interrupt event counter (ETPS[INTCNT]) register bits. That is, when the specified event occurs the ETPS[INTCNT] bits are incremented until they reach the value specified by ETPS[INTPRD]. When ETPS[INTCNT] = ETPS[INTPRD] the counter stops counting and its output is set. The counter is only cleared when an interrupt is sent to the interrupt controller.

When ETPS[INTCNT] reaches ETPS[INTPRD], one of the following behaviors will occur:

- If interrupts are enabled, ETSEL[INTEN] = 1 and the interrupt flag is clear, ETFLG[INT] = 0, then an interrupt pulse is generated and the interrupt flag is set, ETFLG[INT] = 1, and the event counter is cleared ETPS[INTCNT] = 0. The counter will begin counting events again.
- If interrupts are disabled, ETSEL[INTEN] = 0, or the interrupt flag is set, ETFLG[INT] = 1, the counter stops counting events when it reaches the period value ETPS[INTCNT] = ETPS[INTPRD].
- If interrupts are enabled, but the interrupt flag is already set, then the counter will hold its output high until the ENTFLG[INT] flag is cleared. This allows for one interrupt to be pending while one is serviced.

Writing to the INTPRD bits will automatically clear the counter INTCNT = 0 and the counter output will be reset (so no interrupts are generated). Writing a 1 to the ETFRC[INT] bit will increment the event counter INTCNT. The counter will behave as described above when INTCNT = INTPRD. When INTPRD = 0, the counter is disabled and hence no events will be detected and the ETFRC[INT] bit is also ignored.

Note that the interrupts coming from the ePWM module are also used as DMA events. The interrupt registers should be used to enable and clear the current DMA event in order for the ePWM module to generate subsequent DMA events.

Figure 15-47. Event-Trigger Interrupt Generator

15.2.2.10 High-Resolution PWM (HRPWM) Submodule

Figure 15-48 shows the high-resolution PWM (HRPWM) submodule in the ePWM system. Some devices include the high-resolution PWM submodule, see Section 15.1.2 to determine which ePWM instances include this feature.

Figure 15-48. HRPWM System Interface

**15.2.2.10.1 Purpose of the High-Resolution PWM Submodule**

The enhanced high-resolution pulse-width modulator (eHRPWM) extends the time resolution capabilities of the conventionally derived digital pulse-width modulator (PWM). HRPWM is typically used when PWM resolution falls below ~9-10 bits. The key features of HRPWM are:

- Extended time resolution capability
- Used in both duty cycle and phase-shift control methods
- Finer time granularity control or edge positioning using extensions to the Compare A and Phase registers
- Implemented using the A signal path of PWM, that is, on the EPWMxA output. EPWMxB output has conventional PWM capabilities

The ePWM peripheral is used to perform a function that is mathematically equivalent to a digital-to-analog converter (DAC). As shown in Figure 15-49, the effective resolution for conventionally generated PWM is a function of PWM frequency (or period) and system clock frequency.

**Figure 15-49. Resolution Calculations for Conventionally Generated PWM**

If the required PWM operating frequency does not offer sufficient resolution in PWM mode, you may want to consider HRPWM. As an example of improved performance offered by HRPWM, Table 15-39 shows resolution in bits for various PWM frequencies. Table 15-39 values assume a MEP step size of 180 ps. See your device-specific data manual for typical and maximum performance specifications for the MEP.

**Table 15-39. Resolution for PWM and HRPWM**

PWM Frequency (kHz)	Regular Resolution (PWM)		High Resolution (HRPWM)	
	Bits	%	Bits	%
20	12.3	0.0	18.1	0.000
50	11.0	0.0	16.8	0.001
100	10.0	0.1	15.8	0.002
150	9.4	0.2	15.2	0.003
200	9.0	0.2	14.8	0.004
250	8.6	0.3	14.4	0.005
500	7.6	0.5	13.8	0.007
1000	6.6	1.0	12.4	0.018
1500	6.1	1.5	11.9	0.027
2000	5.6	2.0	11.4	0.036

Although each application may differ, typical low-frequency PWM operation (below 250 kHz) may not require HRPWM. HRPWM capability is most useful for high-frequency PWM requirements of power conversion topologies such as:

- Single-phase buck, boost, and flyback
- Multi-phase buck, boost, and flyback
- Phase-shifted full bridge
- Direct modulation of D-Class power amplifiers

### 15.2.2.10.2 Architecture of the High-Resolution PWM Submodule

The HRPWM is based on micro edge positioner (MEP) technology. MEP logic is capable of positioning an edge very finely by sub-dividing one coarse system clock of a conventional PWM generator. The time step accuracy is on the order of 150 ps. The HRPWM also has a self-check software diagnostics mode to check if the MEP logic is running optimally, under all operating conditions.

Figure 15-50 shows the relationship between one coarse system clock and edge position in terms of MEP steps, which are controlled via an 8-bit field in the Compare A extension register (CMPAHR).

**Figure 15-50. Operating Logic Using MEP**

A For MEP range and rounding adjustment.

To generate an HRPWM waveform, configure the TBM, CCM, and AQM registers as you would to generate a conventional PWM of a given frequency and polarity. The HRPWM works together with the TBM, CCM, and AQM registers to extend edge resolution, and should be configured accordingly. Although many programming combinations are possible, only a few are needed and practical.

### 15.2.2.10.3 Controlling and Monitoring the High-Resolution PWM Submodule

The MEP of the HRPWM is controlled by two extension registers, each 8-bits wide. These two HRPWM registers are concatenated with the 16-bit TBPHS and CMPA registers used to control PWM operation.

- TBPHSHR - Time-Base Phase High-Resolution Register
- CMPAHR - Counter-Compare A High-Resolution Register

Table 15-40 lists the registers used to control and monitor the high-resolution PWM submodule.

**Table 15-40. HRPWM Submodule Registers**

Acronym	Register Description	Address Offset	Shadowed
TBPHSHR	Extension Register for HRPWM Phase	4h	No
CMPAHR	Extension Register for HRPWM Duty	10h	Yes
HRCNFG	HRPWM Configuration Register	1040h	No

#### 15.2.2.10.4 Configuring the High-Resolution PWM Submodule

Once the ePWM has been configured to provide conventional PWM of a given frequency and polarity, the HRPWM is configured by programming the HRCNFG register located at offset address 1040h. This register provides configuration options for the following key operating modes:

- **Edge Mode:** The MEP can be programmed to provide precise position control on the rising edge (RE), falling edge (FE), or both edges (BE) at the same time. FE and RE are used for power topologies requiring duty cycle control, while BE is used for topologies requiring phase shifting, for example, phase shifted full bridge.
- **Control Mode:** The MEP is programmed to be controlled either from the CMPAHR register (duty cycle control) or the TBPHSHR register (phase control). RE or FE control mode should be used with CMPAHR register. BE control mode should be used with TBPHSHR register.
- **Shadow Mode:** This mode provides the same shadowing (double buffering) option as in regular PWM mode. This option is valid only when operating from the CMPAHR register and should be chosen to be the same as the regular load option for the CMPA register. If TBPHSHR is used, then this option has no effect.

#### 15.2.2.10.5 Operational Highlights for the High-Resolution PWM Submodule

The MEP logic is capable of placing an edge in one of 255 (8 bits) discrete time steps, each of which has a time resolution on the order of 150 ps. The MEP works with the TBM and CCM registers to be certain that time steps are optimally applied and that edge placement accuracy is maintained over a wide range of PWM frequencies, system clock frequencies and other operating conditions. [Table 15-41](#) shows the typical range of operating frequencies supported by the HRPWM.

**Table 15-41. Relationship Between MEP Steps, PWM Frequency and Resolution**

System (MHz)	MEP Steps Per SYSCLKOUT <sup>(1)</sup> <sup>(2)</sup> <sup>(3)</sup>	PWM Minimum (Hz) <sup>(4)</sup>	PWM Maximum (MHz)	Resolution at Maximum (Bits) <sup>(5)</sup>
50.0	111	763	2.50	11.1
60.0	93	916	3.00	10.9
70.0	79	1068	3.50	10.6
80.0	69	1221	4.00	10.4
90.0	62	1373	4.50	10.3
100.0	56	1526	5.00	10.1

<sup>(1)</sup> System frequency = SYSCLKOUT, that is, CPU clock. TBCLK = SYSCLKOUT

<sup>(2)</sup> Table data based on a MEP time resolution of 180 ps (this is an example value)

<sup>(3)</sup> MEP steps applied =  $T_{\text{SYSCLKOUT}}/180 \text{ ps}$  in this example.

<sup>(4)</sup> PWM minimum frequency is based on a maximum period value, TBPRD = 65 535. PWM mode is asymmetrical up-count.

<sup>(5)</sup> Resolution in bits is given for the maximum PWM frequency stated.

### 15.2.2.10.5.1 Edge Positioning

In a typical power control loop (switch modes, digital motor control (DMC), uninterruptible power supply (UPS)), a digital controller (PID, 2pole/2zero, lag/lead, etc.) issues a duty command, usually expressed in a per unit or percentage terms.

In the following example, assume that for a particular operating point, the demanded duty cycle is 0.405 or 40.5% on-time and the required converter PWM frequency is 1.25 MHz. In conventional PWM generation with a system clock of 100 MHz, the duty cycle choices are in the vicinity of 40.5%. In [Figure 15-51](#), a compare value of 32 counts (duty = 40%) is the closest to 40.5% that you can attain. This is equivalent to an edge position of 320 ns instead of the desired 324 ns. This data is shown in [Table 15-42](#).

By utilizing the MEP, you can achieve an edge position much closer to the desired point of 324 ns. [Table 15-42](#) shows that in addition to the CMPA value, 22 steps of the MEP (CMPAHR register) will position the edge at 323.96 ns, resulting in almost zero error. In this example, it is assumed that the MEP has a step resolution of 180 ns.

**Figure 15-51. Required PWM Waveform for a Requested Duty = 40.5%**

**Table 15-42. CMPA vs Duty (left), and [CMPA:CMPAHR] vs Duty (right)**

CMPA (count) <sup>(1)</sup> <sup>(2)</sup> <sup>(3)</sup>	DUTY (%)	High Time (ns)	CMPA (count)	CMPAHR (count)	Duty (%)	High Time (ns)
28	35.0	280	32	18	40.405	323.24
29	36.3	290	32	19	40.428	323.42
30	37.5	300	32	20	40.450	323.60
31	38.8	310	32	21	40.473	323.78
32	40.0	320	32	22	40.495	323.96
33	41.3	330	32	23	40.518	324.14
34	42.5	340	32	24	40.540	324.32
			32	25	40.563	324.50
Required			32	26	40.585	324.68
32.40	40.5	324	32	27	40.608	324.86

<sup>(1)</sup> System clock, SYSCLKOUT and TBCLK = 100 MHz, 10 ns

<sup>(2)</sup> For a PWM Period register value of 80 counts, PWM Period = 80 × 10 ns = 800 ns, PWM frequency = 1/800 ns = 1.25 MHz

<sup>(3)</sup> Assumed MEP step size for the above example = 180 ps

### 15.2.2.10.5.2 Scaling Considerations

The mechanics of how to position an edge precisely in time has been demonstrated using the resources of the standard (CMPA) and MEP (CMPAHR) registers. In a practical application, however, it is necessary to seamlessly provide the CPU a mapping function from a per-unit (fractional) duty cycle to a final integer (non-fractional) representation that is written to the [CMPA:CMPAHR] register combination.

To do this, first examine the scaling or mapping steps involved. It is common in control software to express duty cycle in a per-unit or percentage basis. This has the advantage of performing all needed math calculations without concern for the final absolute duty cycle, expressed in clock counts or high time in ns. Furthermore, it makes the code more transportable across multiple converter types running different PWM frequencies.

To implement the mapping scheme, a two-step scaling procedure is required.

Assumptions for this example:

System clock, SYSCLKOUT	= 10 ns (100 MHz)
PWM frequency	= 1.25 MHz (1/800 ns)
Required PWM duty cycle, <b>PWMDuty</b>	= 0.405 (40.5%)
PWM period in terms of coarse steps, <b>PWMperiod</b> (800 ns/10 ns)	= 80
Number of MEP steps per coarse step at 180 ps (10 ns/180 ps), <b>MEP_SF</b>	= 55
Value to keep CMPAHR within the range of 1-255 and fractional rounding constant (default value)	= 180h

#### Step 1: Percentage Integer Duty value conversion for CMPA register

CMPA register value	= $\text{int}(\text{PWMDuty} \times \text{PWMperiod})$ ; int means integer part
	= $\text{int}(0.405 \times 80)$
	= $\text{int}(32.4)$
CMPA register value	= 32 (20h)

#### Step 2: Fractional value conversion for CMPAHR register

CMPAHR register value	= $(\text{frac}(\text{PWMDuty} \times \text{PWMperiod}) \times \text{MEP\_SF}) \ll 8) + 180\text{h}$ ; frac means fractional part
	= $(\text{frac}(32.4) \times 55 \ll 8) + 180\text{h}$ ; Shift is to move the value as CMPAHR high byte
	= $((0.4 \times 55) \ll 8) + 180\text{h}$
	= $(22 \ll 8) + 180\text{h}$
	= $22 \times 256 + 180\text{h}$ ; Shifting left by 8 is the same multiplying by 256.
	= $5632 + 180\text{h}$
	= $1600\text{h} + 180\text{h}$
CMPAHR value	= 1780h; CMPAHR value = 1700h, lower 8 bits will be ignored by hardware.

### 15.2.2.10.5.3 Duty Cycle Range Limitation

In high resolution mode, the MEP is not active for 100% of the PWM period. It becomes operational 3 SYCLK cycles after the period starts.

Duty cycle range limitations are illustrated in Figure 15-52. This limitation imposes a lower duty cycle limit on the MEP. For example, precision edge control is not available all the way down to 0% duty cycle. Although for the first 3 or 6 cycles, the HRPWM capabilities are not available, regular PWM duty control is still fully operational down to 0% duty. In most applications this should not be an issue as the controller regulation point is usually not designed to be close to 0% duty cycle.

**Figure 15-52. Low % Duty Cycle Range Limitation Example When PWM Frequency = 1 MHz**

If the application demands HRPWM operation in the low percent duty cycle region, then the HRPWM can be configured to operate in count-down mode with the rising edge position (REP) controlled by the MEP. This is illustrated in Figure 15-53. In this case low percent duty limitation is no longer an issue.

**Figure 15-53. High % Duty Cycle Range Limitation Example when PWM Frequency = 1 MHz**

### 15.2.3 Use Cases

An ePWM module has all the local resources necessary to operate completely as a standalone module or to operate in synchronization with other identical ePWM modules.

#### 15.2.3.1 Overview of Multiple Modules

Previously in this user's guide, all discussions have described the operation of a single module. To facilitate the understanding of multiple modules working together in a system, the ePWM module described in reference is represented by the more simplified block diagram shown in [Figure 15-54](#). This simplified ePWM block shows only the key resources needed to explain how a multiswitch power topology is controlled with multiple ePWM modules working together.

**Figure 15-54. Simplified ePWM Module**

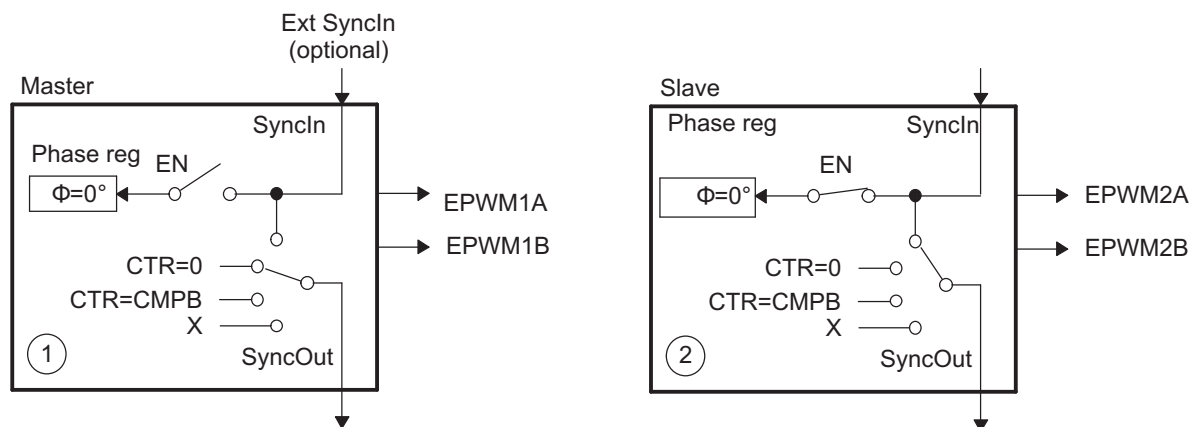

### 15.2.3.2 Key Configuration Capabilities

The key configuration choices available to each module are as follows:

- Options for SyncIn
  - Load own counter with phase register on an incoming sync strobe—enable (EN) switch closed
  - Do nothing or ignore incoming sync strobe—enable switch open
  - Sync flow-through - SyncOut connected to SyncIn
  - Master mode, provides a sync at PWM boundaries—SyncOut connected to CTR = PRD
  - Master mode, provides a sync at any programmable point in time—SyncOut connected to CTR = CMPB
  - Module is in standalone mode and provides No sync to other modules—SyncOut connected to X (disabled)
- Options for SyncOut
  - Sync flow-through - SyncOut connected to SyncIn
  - Master mode, provides a sync at PWM boundaries—SyncOut connected to CTR = PRD
  - Master mode, provides a sync at any programmable point in time—SyncOut connected to CTR = CMPB
  - Module is in standalone mode and provides No sync to other modules—SyncOut connected to X (disabled)

For each choice of SyncOut, a module may also choose to load its own counter with a new phase value on a SyncIn strobe input or choose to ignore it, i.e., via the enable switch. Although various combinations are possible, the two most common—master module and slave module modes—are shown in [Figure 15-55](#).

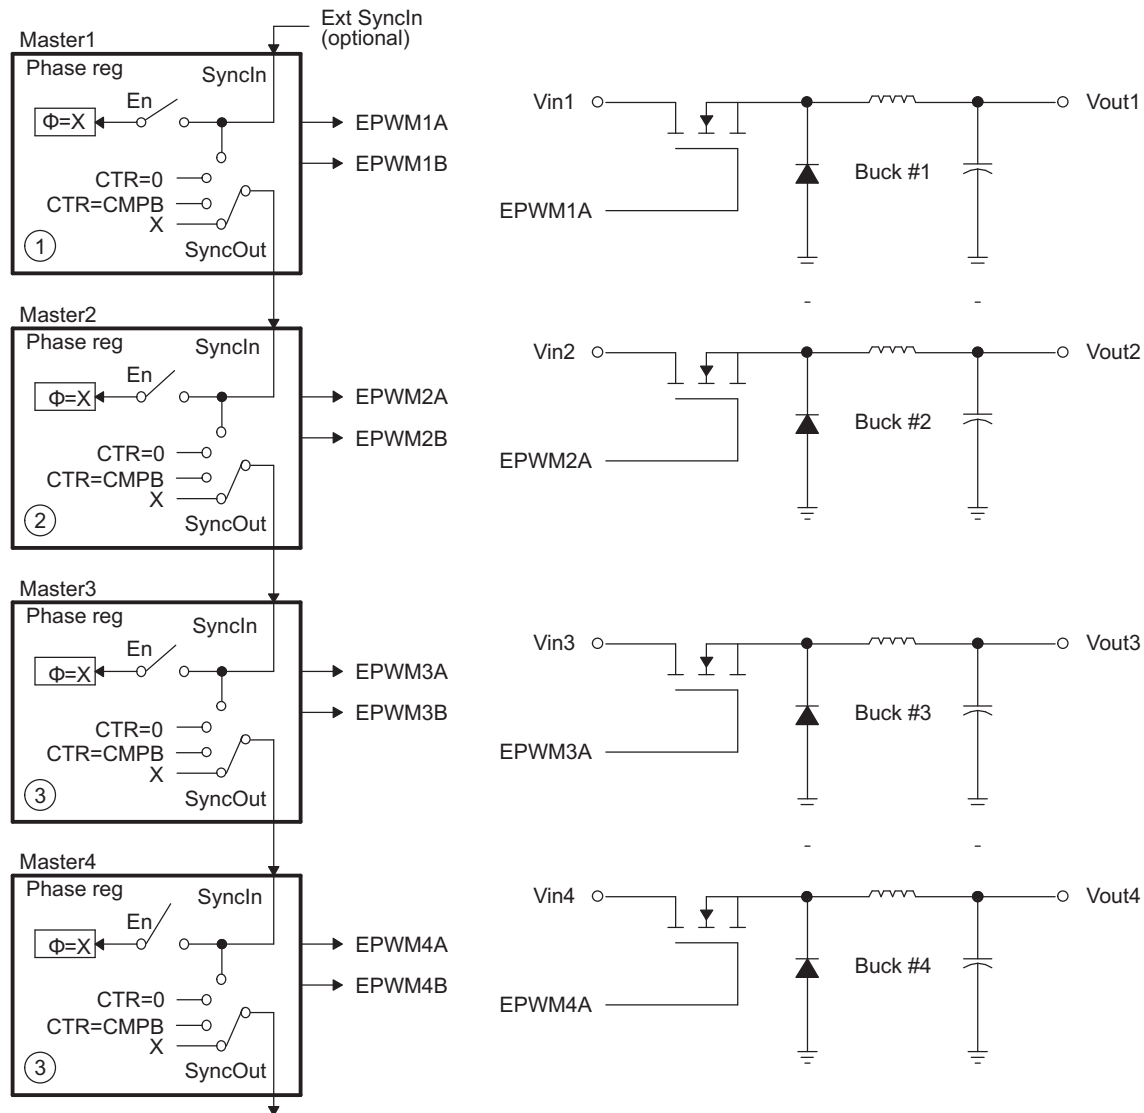

**Figure 15-55. EPWM1 Configured as a Typical Master, EPWM2 Configured as a Slave**

### 15.2.3.3 Controlling Multiple Buck Converters With Independent Frequencies

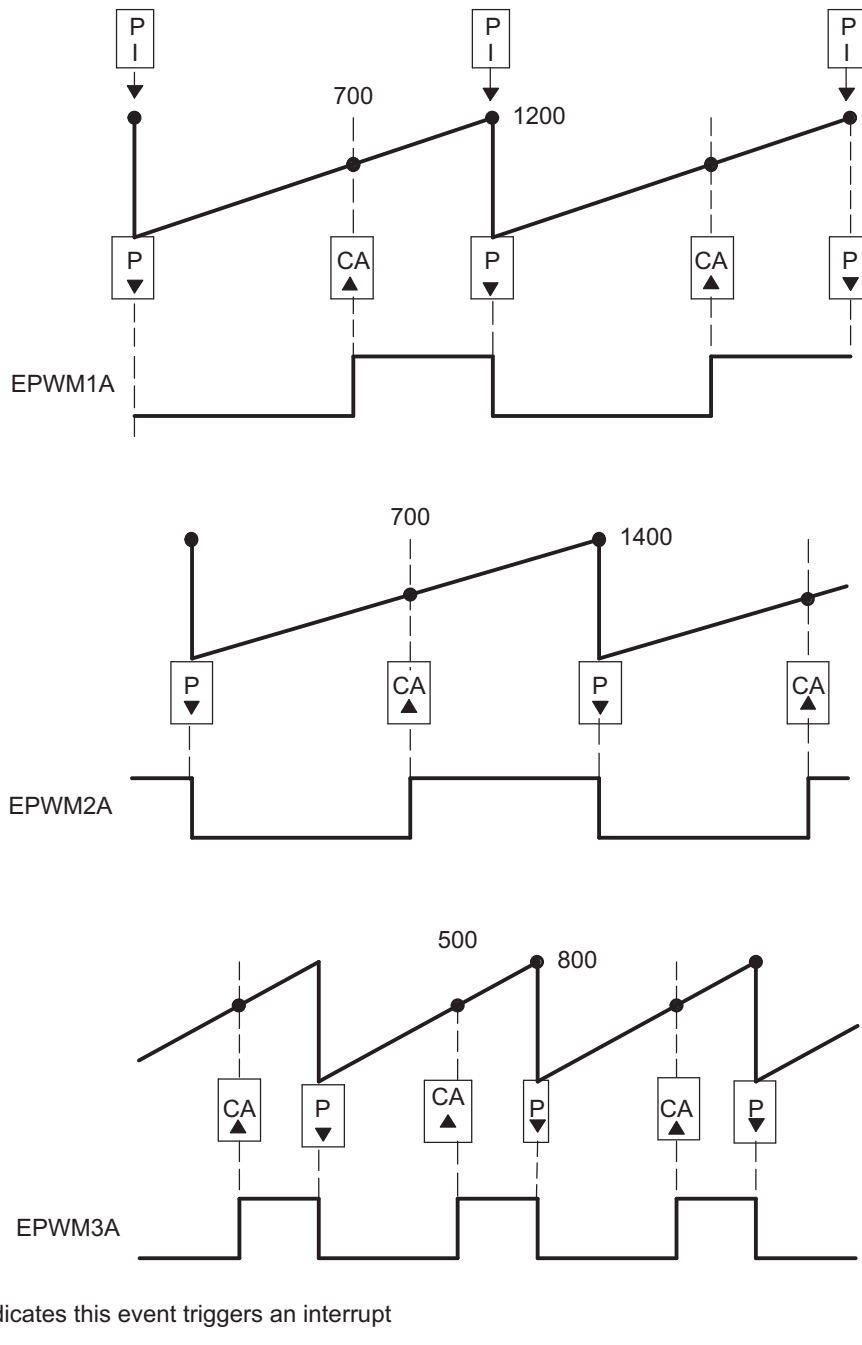

One of the simplest power converter topologies is the buck. A single ePWM module configured as a master can control two buck stages with the same PWM frequency. If independent frequency control is required for each buck converter, then one ePWM module must be allocated for each converter stage. Figure 15-56 shows four buck stages, each running at independent frequencies. In this case, all four ePWM modules are configured as Masters and no synchronization is used. Figure 15-57 shows the waveforms generated by the setup shown in Figure 15-56; note that only three waveforms are shown, although there are four stages.

Figure 15-56. Control of Four Buck Stages. Here  $F_{P_{WM1}} \neq F_{P_{WM2}} \neq F_{P_{WM3}} \neq F_{P_{WM4}}$

NOTE:  $\Theta = X$  indicates value in phase register is a "don't care"

EPwm3Regs.CMPA.half.CMPA = 500;           // adjust duty for output EPWM3A
```

**15.2.3.4 Controlling Multiple Buck Converters With Same Frequencies**

If synchronization is a requirement, ePWM module 2 can be configured as a slave and can operate at integer multiple (N) frequencies of module 1. The sync signal from master to slave ensures these modules remain locked. Figure 15-58 shows such a configuration; Figure 15-59 shows the waveforms generated by the configuration.

```

### 15.2.3.5 Controlling Multiple Half H-Bridge (HHB) Converters

Topologies that require control of multiple switching elements can also be addressed with these same ePWM modules. It is possible to control a Half-H bridge stage with a single ePWM module. This control can be extended to multiple stages. Figure 15-60 shows control of two synchronized Half-H bridge stages where stage 2 can operate at integer multiple (N) frequencies of stage 1. Figure 15-61 shows the waveforms generated by the configuration shown in Figure 15-60.

Module 2 (slave) is configured for Sync flow-through; if required, this configuration allows for a third Half-H bridge to be controlled by PWM module 3 and also, most importantly, to remain in synchronization with master module 1.

Figure 15-60. Control of Two Half-H Bridge Stages ( $F_{P_{WM2}} = N \times F_{P_{WM1}}$ )

EPwm2Regs.CMPB = 250; // adjust duty for output EPWM2B

```

### 15.2.3.6 Controlling Dual 3-Phase Inverters for Motors (ACI and PMSM)

The idea of multiple modules controlling a single power stage can be extended to the 3-phase Inverter case. In such a case, six switching elements can be controlled using three PWM modules, one for each leg of the inverter. Each leg must switch at the same frequency and all legs must be synchronized. A master + two slaves configuration can easily address this requirement. Figure 15-62 shows how six PWM modules can control two independent 3-phase Inverters; each running a motor.

As in the cases shown in the previous sections, we have a choice of running each inverter at a different frequency (module 1 and module 4 are masters as in Figure 15-62), or both inverters can be synchronized by using one master (module 1) and five slaves. In this case, the frequency of modules 4, 5, and 6 (all equal) can be integer multiples of the frequency for modules 1, 2, 3 (also all equal).

**Figure 15-62. Control of Dual 3-Phase Inverter Stages as Is Commonly Used in Motor Control**

### 15.2.3.7 Practical Applications Using Phase Control Between PWM Modules

So far, none of the examples have made use of the phase register (TBPHS). It has either been set to zero or its value has been a don't care. However, by programming appropriate values into TBPHS, multiple PWM modules can address another class of power topologies that rely on phase relationship between legs (or stages) for correct operation. As described in the TB module section, a PWM module can be configured to allow a SyncIn pulse to cause the TBPHS register to be loaded into the TBCNT register. To illustrate this concept, [Figure 15-64](#) shows a master and slave module with a phase relationship of 120°, that is, the slave leads the master.

**Figure 15-64. Configuring Two PWM Modules for Phase Control**

[Figure 15-65](#) shows the associated timing waveforms for this configuration. Here, TBPRD = 600 for both master and slave. For the slave, TBPHS = 200 ( $200/600 \times 360^\circ = 120^\circ$ ). Whenever the master generates a SyncIn pulse (CTR = PRD), the value of TBPHS = 200 is loaded into the slave TBCNT register so the slave time-base is always leading the master's time-base by 120°.

**Figure 15-65. Timing Waveforms Associated With Phase Control Between 2 Modules**

### 15.2.3.8 Controlling a 3-Phase Interleaved DC/DC Converter

A popular power topology that makes use of phase-offset between modules is shown in [Figure 15-66](#). This system uses three PWM modules, with module 1 configured as the master. To work, the phase relationship between adjacent modules must be  $F = 120^\circ$ . This is achieved by setting the slave TBPHS registers 2 and 3 with values of 1/3 and 2/3 of the period value, respectively. For example, if the period register is loaded with a value of 600 counts, then TBPHS (slave 2) = 200 and TBPHS (slave 3) = 400. Both slave modules are synchronized to the master 1 module.

This concept can be extended to four or more phases, by setting the TBPHS values appropriately. The following formula gives the TBPHS values for N phases:

$$TBPHS(N,M) = (TBPRD/N) \times (M - 1)$$

Where:

N = number of phases

M = PWM module number

For example, for the 3-phase case (N = 3), TBPRD = 600,

$$TBPHS(3,2) = (600/3) \times (2 - 1) = 200 \times 1 = 200 \text{ (Phase value for Slave module 2)}$$

$$TBPHS(3,3) = (600/3) \times (3 - 1) = 200 \times 2 = 400 \text{ (Phase value for Slave module 3)}$$

[Figure 15-67](#) shows the waveforms for the configuration in [Figure 15-66](#).

```

### 15.2.3.9 Controlling Zero Voltage Switched Full Bridge (ZVSFB) Converter

The example given in [Figure 15-68](#) assumes a static or constant phase relationship between legs (modules). In such a case, control is achieved by modulating the duty cycle. It is also possible to dynamically change the phase value on a cycle-by-cycle basis. This feature lends itself to controlling a class of power topologies known as *phase-shifted full bridge*, or *zero voltage switched full bridge*. Here the controlled parameter is not duty cycle (this is kept constant at approximately 50 percent); instead it is the phase relationship between legs. Such a system can be implemented by allocating the resources of two PWM modules to control a single power stage, which in turn requires control of four switching elements. [Figure 15-69](#) shows a master/slave module combination synchronized together to control a full H-bridge. In this case, both master and slave modules are required to switch at the same PWM frequency. The phase is controlled by using the slave's phase register (TBPHS). The master's phase register is not used and therefore can be initialized to zero.

**Figure 15-68. Controlling a Full-H Bridge Stage ( $F_{PWM2} = F_{PWM1}$ )**

DBCTL	MODE	DB_FULL_ENABLE	Enable Dead-band module
	POLSEL	DB_ACTV_HIC	Active Hi complementary
DBFED	DBFED	30	FED = 30 TBCLKs
	DBRED	40	RED = 40 TBCLKs

**Example 15-8. Code Snippet for Configuration in Figure 15-68**

```
// Run Time (Note: Example execution of one run-time instance)
//=====
EPwm2Regs.TBPHS = 1200-300;           // Set Phase reg to 300/1200 * 360 = 90 deg
EPwm1Regs.DBFED = FED1_NewValue;     // Update ZVS transition interval
EPwm1Regs.DBRED = RED1_NewValue;     // Update ZVS transition interval
EPwm2Regs.DBFED = FED2_NewValue;     // Update ZVS transition interval
EPwm2Regs.DBRED = RED2_NewValue;     // Update ZVS transition interval
```

## 15.2.4 Registers

**Table 15-58. ePWM Module Control and Status Registers Grouped by Submodule**

Acronym	Offset <sup>(1)</sup>	Size (x16)	Shadow	Register Description
<b>Time-Base Submodule Registers (Section 15.2.4.1)</b>				
TBCTL	0h	1	No	Time-Base Control Register
TBSTS	2h	1	No	Time-Base Status Register
TBPHSHR	4h	1	No	Extension for HRPWM Phase Register <sup>(2)</sup>
TBPHS	6h	1	No	Time-Base Phase Register
TBCNT	8h	1	No	Time-Base Counter Register
TBPRD	Ah	1	Yes	Time-Base Period Register
<b>Counter-Compare Submodule Registers (Section 15.2.4.2)</b>				
CMPCTL	Eh	1	No	Counter-Compare Control Register
CMPAHR	10h	1	No	Extension for HRPWM Counter-Compare A Register <sup>(2)</sup>
CMPA	12h	1	Yes	Counter-Compare A Register
CMPB	14h	1	Yes	Counter-Compare B Register
<b>Action-Qualifier Submodule Registers (Section 15.2.4.3)</b>				
AQCTLA	16h	1	No	Action-Qualifier Control Register for Output A (EPWMxA)
AQCTLB	18h	1	No	Action-Qualifier Control Register for Output B (EPWMxB)
AQSFRC	1Ah	1	No	Action-Qualifier Software Force Register
AQCSFRC	1Ch	1	Yes	Action-Qualifier Continuous S/W Force Register Set
<b>Dead-Band Generator Submodule Registers (Section 15.2.4.4)</b>				
DBCTL	1Eh	1	No	Dead-Band Generator Control Register
DBRED	20h	1	No	Dead-Band Generator Rising Edge Delay Count Register
DBFED	22h	1	No	Dead-Band Generator Falling Edge Delay Count Register
<b>Trip-Zone Submodule Registers (Section 15.2.4.5)</b>				
TZSEL	24h	1	No	Trip-Zone Select Register
TZCTL	28h	1	No	Trip-Zone Control Register
TZEINT	2Ah	1	No	Trip-Zone Enable Interrupt Register
TZFLG	2Ch	1	No	Trip-Zone Flag Register
TZCLR	2Eh	1	No	Trip-Zone Clear Register
TZFRC	30h	1	No	Trip-Zone Force Register
<b>Event-Trigger Submodule Registers (Section 15.2.4.6)</b>				
ETSEL	32h	1	No	Event-Trigger Selection Register
ETPS	34h	1	No	Event-Trigger Pre-Scale Register
ETFLG	36h	1	No	Event-Trigger Flag Register
ETCLR	38h	1	No	Event-Trigger Clear Register
ETFRC	3Ah	1	No	Event-Trigger Force Register
<b>PWM-Chopper Submodule Registers (Section 15.2.4.7)</b>				
PCCTL	3Ch	1	No	PWM-Chopper Control Register
<b>High-Resolution PWM (HRPWM) Submodule Registers (Section 15.2.4.8)</b>				
HRCTL	40h	1	No	HRPWM Control Register <sup>(2)</sup>

<sup>(1)</sup> Locations not shown are reserved.

<sup>(2)</sup> These registers are only available on ePWM instances that include the high-resolution PWM (HRPWM) extension; otherwise, these locations are reserved. See [Section 15.1.2](#) to determine which instances include the HRPWM.

### 15.2.4.1 Time-Base Submodule Registers

Table 15-59 lists the memory-mapped registers for the time-base submodule. All other register offset addresses not listed in Table 15-59 should be considered as reserved locations and the register contents should not be modified.

**Table 15-59. Time-Base Submodule Registers**

Offset	Acronym	Register Description	Section
0h	TBCTL	Time-Base Control Register	<a href="#">Section 15.2.4.1.1</a>
2h	TBSTS	Time-Base Status Register	<a href="#">Section 15.2.4.1.2</a>
4h	TBPHSHR	Time-Base Phase High-Resolution Register <sup>(1)</sup>	<a href="#">Section 15.2.4.8.1</a>
6h	TBPHS	Time-Base Phase Register	<a href="#">Section 15.2.4.1.3</a>
8h	TBCNT	Time-Base Counter Register	<a href="#">Section 15.2.4.1.4</a>
Ah	TBPRD	Time-Base Period Register	<a href="#">Section 15.2.4.1.5</a>

<sup>(1)</sup> This register is only available on ePWM instances that include the high-resolution PWM (HRPWM) extension; otherwise, this location is reserved.

#### 15.2.4.1.1 Time-Base Control Register (TBCTL)

The time-base control register (TBCTL) is shown in Figure 15-70 and described in Table 15-60.

**Figure 15-70. Time-Base Control Register (TBCTL)**

15	14	13	12	10	9	8	
FREE, SOFT		PHSDIR	CLKDIV		HSPCLKDIV		
R/W-0		R/W-0	R/W-0		R/W-0		
7	6	5	4	3	2	1	0
HSPCLKDIV	SWFSYNC	SYNCOSEL		PRDLD	PHSEN	CTRMODE	
R/W-1	R/W-0	R/W-0		R/W-0	R/W-0	R/W-3h	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-60. Time-Base Control Register (TBCTL) Field Descriptions**

Bit	Field	Value	Description
15-14	FREE, SOFT	0-3h	Emulation Mode Bits. These bits select the behavior of the ePWM time-base counter during emulation events:
		0	Stop after the next time-base counter increment or decrement
		1h	Stop when counter completes a whole cycle: <ul style="list-style-type: none"> <li>Up-count mode: stop when the time-base counter = period (TBCNT = TBPRD)</li> <li>Down-count mode: stop when the time-base counter = 0000 (TBCNT = 0000h)</li> <li>Up-down-count mode: stop when the time-base counter = 0000 (TBCNT = 0000h)</li> </ul>
		2h-3h	Free run
13	PHSDIR		Phase Direction Bit. This bit is only used when the time-base counter is configured in the up-down-count mode. The PHSDIR bit indicates the direction the time-base counter (TBCNT) will count after a synchronization event occurs and a new phase value is loaded from the phase (TBPHS) register. This is irrespective of the direction of the counter before the synchronization event..
			In the up-count and down-count modes this bit is ignored.
		0	Count down after the synchronization event.
		1	Count up after the synchronization event.

**Table 15-60. Time-Base Control Register (TBCTL) Field Descriptions (continued)**

Bit	Field	Value	Description
12:10	CLKDIV	0-7h 0 1h 2h 3h 4h 5h 6h 7h	Time-base Clock Prescale Bits. These bits determine part of the time-base clock prescale value. $TBCLK = SYSCLKOUT / (HSPCLKDIV \times CLKDIV)$ /1 (default on reset) /2 /4 /8 /16 /32 /64 /128
9-7	HSPCLKDIV	0-7h 0 1h 2h 3h 4h 5h 6h 7h	High-Speed Time-base Clock Prescale Bits. These bits determine part of the time-base clock prescale value. $TBCLK = SYSCLKOUT / (HSPCLKDIV \times CLKDIV)$ This divisor emulates the HSPCLK in the TMS320x281x system as used on the Event Manager (EV) peripheral. /1 /2 (default on reset) /4 /6 /8 /10 /12 /14
6	SWFSYNC	0 1	Software Forced Synchronization Pulse Writing a 0 has no effect and reads always return a 0. Writing a 1 forces a one-time synchronization pulse to be generated. This event is ORed with the EPWMxSYNCl input of the ePWM module. SWFSYNC is valid (operates) only when EPWMxSYNCl is selected by SYNCOSSEL = 00.
5-4	SYNCOSSEL	0-3h 0 1h 2h 3h	Synchronization Output Select. These bits select the source of the EPWMxSYNCO signal. EPWMxSYNCO: CTR = 0: Time-base counter equal to zero (TBCNT = 0000h) CTR = CMPB : Time-base counter equal to counter-compare B (TBCNT = CMPB) Disable EPWMxSYNCO signal
3	PRDL	0 1	Active Period Register Load From Shadow Register Select 0 The period register (TBPRD) is loaded from its shadow register when the time-base counter, TBCNT, is equal to zero. A write or read to the TBPRD register accesses the shadow register. 1 Load the TBPRD register immediately without using a shadow register. A write or read to the TBPRD register directly accesses the active register.
2	PHSEN	0 1	Counter Register Load From Phase Register Enable 0 Do not load the time-base counter (TBCNT) from the time-base phase register (TBPHS) 1 Load the time-base counter with the phase register when an EPWMxSYNCl input signal occurs or when a software synchronization is forced by the SWFSYNC bit.

**Table 15-60. Time-Base Control Register (TBCTL) Field Descriptions (continued)**

Bit	Field	Value	Description
1-0	CTRMODE	0-3h	Counter Mode. The time-base counter mode is normally configured once and not changed during normal operation. If you change the mode of the counter, the change will take effect at the next TBCLK edge and the current counter value shall increment or decrement from the value before the mode change.  These bits set the time-base counter mode of operation as follows:
		0	Up-count mode
		1h	Down-count mode
		2h	Up-down-count mode
		3h	Stop-freeze counter operation (default on reset)

#### 15.2.4.1.2 Time-Base Status Register (TBSTS)

The time-base status register (TBSTS) is shown in [Figure 15-71](#) and described in [Table 15-61](#).

**Figure 15-71. Time-Base Status Register (TBSTS)**

15	3	2	1	0
Reserved		CTRMAX	SYNCI	CTRDIR
R-0		R/W1C-0	R/W1C-0	R-1

LEGEND: R/W = Read/Write; R/W1C = Read/Write 1 to clear; -n = value after reset

**Table 15-61. Time-Base Status Register (TBSTS) Field Descriptions**

Bit	Field	Value	Description
15-3	Reserved	0	Reserved
2	CTRMAX	0	Time-Base Counter Max Latched Status Bit Reading a 0 indicates the time-base counter never reached its maximum value. Writing a 0 will have no effect.
		1	Reading a 1 on this bit indicates that the time-base counter reached the max value 0xFFFF. Writing a 1 to this bit will clear the latched event.
1	SYNCI	0	Input Synchronization Latched Status Bit Writing a 0 will have no effect. Reading a 0 indicates no external synchronization event has occurred.
		1	Reading a 1 on this bit indicates that an external synchronization event has occurred (EPWMxSYNCI). Writing a 1 to this bit will clear the latched event.
0	CTRDIR	0	Time-Base Counter Direction Status Bit. At reset, the counter is frozen; therefore, this bit has no meaning. To make this bit meaningful, you must first set the appropriate mode via TBCTL[CTRMODE]. Time-Base Counter is currently counting down.
		1	Time-Base Counter is currently counting up.

#### 15.2.4.1.3 Time-Base Phase Register (TBPHS)

The time-base phase register (TBPHS) is shown in [Figure 15-72](#) and described in [Table 15-62](#).

**Figure 15-72. Time-Base Phase Register (TBPHS)**

15	0
TBPHS	
R/W-0	

LEGEND: R/W = Read/Write; -n = value after reset

**Table 15-62. Time-Base Phase Register (TBPHS) Field Descriptions**

Bits	Name	Value	Description
15-0	TBPHS	0-FFFFh	These bits set time-base counter phase of the selected ePWM relative to the time-base that is supplying the synchronization input signal. <ul style="list-style-type: none"> <li>• If TBCTL[PHSEN] = 0, then the synchronization event is ignored and the time-base counter is not loaded with the phase.</li> <li>• If TBCTL[PHSEN] = 1, then the time-base counter (TBCNT) will be loaded with the phase (TBPHS) when a synchronization event occurs. The synchronization event can be initiated by the input synchronization signal (EPWMxSYNCI) or by a software forced synchronization.</li> </ul>

#### 15.2.4.1.4 Time-Base Counter Register (TBCNT)

The time-base counter register (TBCNT) is shown in [Figure 15-73](#) and described in [Table 15-63](#).

**Figure 15-73. Time-Base Counter Register (TBCNT)**

LEGEND: R/W = Read/Write; -n = value after reset

**Table 15-63. Time-Base Counter Register (TBCNT) Field Descriptions**

Bits	Name	Value	Description
15-0	TBCNT	0-FFFFh	Reading these bits gives the current time-base counter value.  Writing to these bits sets the current time-base counter value. The update happens as soon as the write occurs; the write is NOT synchronized to the time-base clock (TBCLK) and the register is not shadowed.

### 15.2.4.1.5 Time-Base Period Register (TBPRD)

The time-base period register (TBPRD) is shown in [Figure 15-74](#) and described in [Table 15-64](#).

**Figure 15-74. Time-Base Period Register (TBPRD)**

LEGEND: R/W = Read/Write; -n = value after reset

**Table 15-64. Time-Base Period Register (TBPRD) Field Descriptions**

Bits	Name	Value	Description
15-0	TBPRD	0-FFFFh	These bits determine the period of the time-base counter. This sets the PWM frequency. Shadowing of this register is enabled and disabled by the TBCTL[PRDL] bit. By default this register is shadowed. <ul style="list-style-type: none"> <li>• If TBCTL[PRDL] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the active register will be loaded from the shadow register when the time-base counter equals zero.</li> <li>• If TBCTL[PRDL] = 1, then the shadow is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware.</li> <li>• The active and shadow registers share the same memory map address.</li> </ul>

### 15.2.4.2 Counter-Compare Submodule Registers

[Table 15-65](#) lists the memory-mapped registers for the counter-compare submodule. All other register offset addresses not listed in [Table 15-65](#) should be considered as reserved locations and the register contents should not be modified.

**Table 15-65. Counter-Compare Submodule Registers**

Offset	Acronym	Register Description	Section
Eh	CMPCTL	Counter-Compare Control Register	<a href="#">Section 15.2.4.2.1</a>
10h	CMPAHR	Counter-Compare A High-Resolution Register <sup>(1)</sup>	<a href="#">Section 15.2.4.8.2</a>
12h	CMPA	Counter-Compare A Register	<a href="#">Section 15.2.4.2.2</a>
14h	CMPB	Counter-Compare B Register	<a href="#">Section 15.2.4.2.3</a>

<sup>(1)</sup> This register is only available on ePWM instances that include the high-resolution PWM (HRPWM) extension; otherwise, this location is reserved.

### 15.2.4.2.1 Counter-Compare Control Register (CMPCTL)

The counter-compare control register (CMPCTL) is shown in [Figure 15-75](#) and described in [Table 15-66](#).

**Figure 15-75. Counter-Compare Control Register (CMPCTL)**

15				10				9		8	
Reserved								SHDWBFULL	SHDWAFULL		
R-0				R-0				R-0		R-0	
7		6		5		4		3		2	
Reserved		SHDWBMODE		Reserved		SHDWAMODE		LOADBMODE		LOADAMODE	
R-0		R/W-0		R-0		R/W-0		R/W-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-66. Counter-Compare Control Register (CMPCTL) Field Descriptions**

Bits	Name	Value	Description
15-10	Reserved	0	Reserved
9	SHDWBFULL	0 1	Counter-compare B (CMPB) Shadow Register Full Status Flag. This bit self clears once a load-strobe occurs. 0 CMPB shadow FIFO not full yet 1 Indicates the CMPB shadow FIFO is full; a CPU write will overwrite current shadow value.
8	SHDWAFULL	0 1	Counter-compare A (CMPA) Shadow Register Full Status Flag. The flag bit is set when a 32-bit write to CMPA:CMPAHR register or a 16-bit write to CMPA register is made. A 16-bit write to CMPAHR register will not affect the flag. This bit self clears once a load-strobe occurs. 0 CMPA shadow FIFO not full yet 1 Indicates the CMPA shadow FIFO is full, a CPU write will overwrite the current shadow value.
7	Reserved	0	Reserved
6	SHDWBMODE	0 1	Counter-compare B (CMPB) Register Operating Mode 0 Shadow mode. Operates as a double buffer. All writes via the CPU access the shadow register. 1 Immediate mode. Only the active compare B register is used. All writes and reads directly access the active register for immediate compare action.
5	Reserved		Reserved
4	SHDWAMODE	0 1	Counter-compare A (CMPA) Register Operating Mode 0 Shadow mode. Operates as a double buffer. All writes via the CPU access the shadow register. 1 Immediate mode. Only the active compare register is used. All writes and reads directly access the active register for immediate compare action
3-2	LOADBMODE	0-3h 0 1h 2h 3h	Active Counter-Compare B (CMPB) Load From Shadow Select Mode. This bit has no effect in immediate mode (CMPCTL[SHDWBMODE] = 1). 0 Load on CTR = 0: Time-base counter equal to zero (TBCNT = 0000h) 1h Load on CTR = PRD: Time-base counter equal to period (TBCNT = TBPRD) 2h Load on either CTR = 0 or CTR = PRD 3h Freeze (no loads possible)
1-0	LOADAMODE	0-3h 0 1h 2h 3h	Active Counter-Compare A (CMPA) Load From Shadow Select Mode. This bit has no effect in immediate mode (CMPCTL[SHDWAMODE] = 1). 0 Load on CTR = 0: Time-base counter equal to zero (TBCNT = 0000h) 1h Load on CTR = PRD: Time-base counter equal to period (TBCNT = TBPRD) 2h Load on either CTR = 0 or CTR = PRD 3h Freeze (no loads possible)

### 15.2.4.2.2 Counter-Compare A Register (CMPA)

The counter-compare A register (CMPA) is shown in [Figure 15-76](#) and described in [Table 15-67](#).

**Figure 15-76. Counter-Compare A Register (CMPA)**

LEGEND: R/W = Read/Write; -n = value after reset

**Table 15-67. Counter-Compare A Register (CMPA) Field Descriptions**

Bits	Name	Value	Description
15-0	CMPA	0-FFFFh	<p>The value in the active CMPA register is continuously compared to the time-base counter (TBCNT). When the values are equal, the counter-compare module generates a "time-base counter equal to counter compare A" event. This event is sent to the action-qualifier where it is qualified and converted into one or more actions. These actions can be applied to either the EPWMxA or the EPWMxB output depending on the configuration of the AQCTLA and AQCTLB registers. The actions that can be defined in the AQCTLA and AQCTLB registers include:</p> <ul style="list-style-type: none"> <li>• Do nothing; the event is ignored.</li> <li>• Clear: Pull the EPWMxA and/or EPWMxB signal low</li> <li>• Set: Pull the EPWMxA and/or EPWMxB signal high</li> <li>• Toggle the EPWMxA and/or EPWMxB signal</li> </ul> <p>Shadowing of this register is enabled and disabled by the CMPCTL[SHDWAMODE] bit. By default this register is shadowed.</p> <ul style="list-style-type: none"> <li>• If CMPCTL[SHDWAMODE] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the CMPCTL[LOADAMODE] bit field determines which event will load the active register from the shadow register.</li> <li>• Before a write, the CMPCTL[SHDWAFULL] bit can be read to determine if the shadow register is currently full.</li> <li>• If CMPCTL[SHDWAMODE] = 1, then the shadow register is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware.</li> <li>• In either mode, the active and shadow registers share the same memory map address.</li> </ul>

### 15.2.4.2.3 Counter-Compare B Register (CMPB)

The counter-compare B register (CMPB) is shown in [Figure 15-77](#) and described in [Table 15-68](#).

**Figure 15-77. Counter-Compare B Register (CMPB)**

15	CMPB	0
R/W-0		

LEGEND: R/W = Read/Write; -n = value after reset

**Table 15-68. Counter-Compare B Register (CMPB) Field Descriptions**

Bits	Name	Value	Description
15-0	CMPB	0-FFFFh	<p>The value in the active CMPB register is continuously compared to the time-base counter (TBCNT). When the values are equal, the counter-compare module generates a "time-base counter equal to counter compare B" event. This event is sent to the action-qualifier where it is qualified and converted into one or more actions. These actions can be applied to either the EPWMxA or the EPWMxB output depending on the configuration of the AQCTLA and AQCTLB registers. The actions that can be defined in the AQCTLA and AQCTLB registers include:</p> <ul style="list-style-type: none"> <li>Do nothing. event is ignored.</li> <li>Clear: Pull the EPWMxA and/or EPWMxB signal low</li> <li>Set: Pull the EPWMxA and/or EPWMxB signal high</li> <li>Toggle the EPWMxA and/or EPWMxB signal</li> </ul> <p>Shadowing of this register is enabled and disabled by the CMPCTL[SHDWBMODE] bit. By default this register is shadowed.</p> <ul style="list-style-type: none"> <li>If CMPCTL[SHDWBMODE] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the CMPCTL[LOADBMODE] bit field determines which event will load the active register from the shadow register:</li> <li>Before a write, the CMPCTL[SHDWBFULL] bit can be read to determine if the shadow register is currently full.</li> <li>If CMPCTL[SHDWBMODE] = 1, then the shadow register is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware.</li> <li>In either mode, the active and shadow registers share the same memory map address.</li> </ul>

### 15.2.4.3 Action-Qualifier Submodule Registers

[Table 15-69](#) lists the memory-mapped registers for the action-qualifier submodule. All other register offset addresses not listed in [Table 15-69](#) should be considered as reserved locations and the register contents should not be modified.

**Table 15-69. Action-Qualifier Submodule Registers**

Offset	Acronym	Register Description	Section
16h	AQCTLA	Action-Qualifier Output A Control Register	<a href="#">Section 15.2.4.3.1</a>
18h	AQCTLB	Action-Qualifier Output B Control Register	<a href="#">Section 15.2.4.3.2</a>
1Ah	AQSFRC	Action-Qualifier Software Force Register	<a href="#">Section 15.2.4.3.3</a>
1Ch	AQCSFRC	Action-Qualifier Continuous Software Force Register	<a href="#">Section 15.2.4.3.4</a>

### 15.2.4.3.1 Action-Qualifier Output A Control Register (AQCTLA)

The action-qualifier output A control register (AQCTLA) is shown in [Figure 15-78](#) and described in [Table 15-70](#).

**Figure 15-78. Action-Qualifier Output A Control Register (AQCTLA)**

15	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				CBD		CBU		CAD		CAU		PRD	
R-0				R/W-0		R/W-0		R/W-0		R/W-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-70. Action-Qualifier Output A Control Register (AQCTLA) Field Descriptions**

Bits	Name	Value	Description
15-12	Reserved	0	Reserved
11-10	CBD	0-3h	Action when the time-base counter equals the active CMPB register and the counter is decrementing.
		0	Do nothing (action disabled)
		1h	Clear: force EPWMxA output low.
		2h	Set: force EPWMxA output high.
3h	Toggle EPWMxA output: low output signal will be forced high, and a high signal will be forced low.		
9-8	CBU	0-3h	Action when the counter equals the active CMPB register and the counter is incrementing.
		0	Do nothing (action disabled)
		1h	Clear: force EPWMxA output low.
		2h	Set: force EPWMxA output high.
3h	Toggle EPWMxA output: low output signal will be forced high, and a high signal will be forced low.		
7-6	CAD	0-3h	Action when the counter equals the active CMPA register and the counter is decrementing.
		0	Do nothing (action disabled)
		1h	Clear: force EPWMxA output low.
		2h	Set: force EPWMxA output high.
3h	Toggle EPWMxA output: low output signal will be forced high, and a high signal will be forced low.		
5-4	CAU	0-3h	Action when the counter equals the active CMPA register and the counter is incrementing.
		0	Do nothing (action disabled)
		1h	Clear: force EPWMxA output low.
		2h	Set: force EPWMxA output high.
3h	Toggle EPWMxA output: low output signal will be forced high, and a high signal will be forced low.		
3-2	PRD	0-3h	Action when the counter equals the period. Note: By definition, in count up-down mode when the counter equals period the direction is defined as 0 or counting down.
		0	Do nothing (action disabled)
		1h	Clear: force EPWMxA output low.
		2h	Set: force EPWMxA output high.
3h	Toggle EPWMxA output: low output signal will be forced high, and a high signal will be forced low.		
1-0	ZRO	0-3h	Action when counter equals zero. Note: By definition, in count up-down mode when the counter equals 0 the direction is defined as 1 or counting up.
		0	Do nothing (action disabled)
		1h	Clear: force EPWMxA output low.
		2h	Set: force EPWMxA output high.
3h	Toggle EPWMxA output: low output signal will be forced high, and a high signal will be forced low.		

### 15.2.4.3.2 Action-Qualifier Output B Control Register (AQCTLB)

The action-qualifier output B control register (AQCTLB) is shown in [Figure 15-79](#) and described in [Table 15-71](#).

**Figure 15-79. Action-Qualifier Output B Control Register (AQCTLB)**

Bits	Name	Value	Description
15-12	Reserved	0	Reserved
11-10	CBD	0-3h	Action when the counter equals the active CMPB register and the counter is decrementing.
		0	Do nothing (action disabled)
		1h	Clear: force EPWMxB output low.
		2h	Set: force EPWMxB output high.
3h	Toggle EPWMxB output: low output signal will be forced high, and a high signal will be forced low.		
9-8	CBU	0-3h	Action when the counter equals the active CMPB register and the counter is incrementing.
		0	Do nothing (action disabled)
		1h	Clear: force EPWMxB output low.
		2h	Set: force EPWMxB output high.
3h	Toggle EPWMxB output: low output signal will be forced high, and a high signal will be forced low.		
7-6	CAD	0-3h	Action when the counter equals the active CMPA register and the counter is decrementing.
		0	Do nothing (action disabled)
		1h	Clear: force EPWMxB output low.
		2h	Set: force EPWMxB output high.
3h	Toggle EPWMxB output: low output signal will be forced high, and a high signal will be forced low.		
5-4	CAU	0-3h	Action when the counter equals the active CMPA register and the counter is incrementing.
		0	Do nothing (action disabled)
		1h	Clear: force EPWMxB output low.
		2h	Set: force EPWMxB output high.
3h	Toggle EPWMxB output: low output signal will be forced high, and a high signal will be forced low.		
3-2	PRD	0-3h	Action when the counter equals the period. Note: By definition, in count up-down mode when the counter equals period the direction is defined as 0 or counting down.
		0	Do nothing (action disabled)
		1h	Clear: force EPWMxB output low.
		2h	Set: force EPWMxB output high.
3h	Toggle EPWMxB output: low output signal will be forced high, and a high signal will be forced low.		
1-0	ZRO	0-3h	Action when counter equals zero. Note: By definition, in count up-down mode when the counter equals 0 the direction is defined as 1 or counting up.
		0	Do nothing (action disabled)
		1h	Clear: force EPWMxB output low.
		2h	Set: force EPWMxB output high.
3h	Toggle EPWMxB output: low output signal will be forced high, and a high signal will be forced low.		

### 15.2.4.3.3 Action-Qualifier Software Force Register (AQSFRC)

The action-qualifier software force register (AQSFRC) is shown in [Figure 15-80](#) and described in [Table 15-72](#).

**Figure 15-80. Action-Qualifier Software Force Register (AQSFRC)**

15	8	7	6	5	4	3	2	1	0
Reserved		RLDCSF	OTSFB	ACTSFB	OTSFA	ACTSFA			
R-0		R/W-0	R/W-0	R/W-0	R/W-0	R/W-0			

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-72. Action-Qualifier Software Force Register (AQSFRC) Field Descriptions**

Bit	Field	Value	Description
15-8	Reserved	0	Reserved
7-6	RLDCSF	0-3h	AQSFRC Active Register Reload From Shadow Options
		0	Load on event counter equals zero
		1h	Load on event counter equals period
		2h	Load on event counter equals zero or counter equals period
		3h	Load immediately (the active register is directly accessed by the CPU and is not loaded from the shadow register).
5	OTSFB	0	One-Time Software Forced Event on Output B
		0	Writing a 0 (zero) has no effect. Always reads back a 0
			This bit is auto cleared once a write to this register is complete, that is, a forced event is initiated.)
			This is a one-shot forced event. It can be overridden by another subsequent event on output B.
		1	Initiates a single s/w forced event
4-3	ACTSFB	0-3h	Action when One-Time Software Force B Is Invoked
		0	Does nothing (action disabled)
		1h	Clear (low)
		2h	Set (high)
		3h	Toggle (Low -> High, High -> Low)
			<b>Note:</b> This action is not qualified by counter direction (CNT_dir)
2	OTSFA	0	One-Time Software Forced Event on Output A
		0	Writing a 0 (zero) has no effect. Always reads back a 0.
			This bit is auto cleared once a write to this register is complete (that is, a forced event is initiated).
		1	Initiates a single software forced event
1-0	ACTSFA	0-3h	Action When One-Time Software Force A Is Invoked
		0	Does nothing (action disabled)
		1h	Clear (low)
		2h	Set (high)
		3h	Toggle (Low → High, High → Low)
			<b>Note:</b> This action is not qualified by counter direction (CNT_dir)

#### 15.2.4.3.4 Action-Qualifier Continuous Software Force Register (AQCSFRC)

The action-qualifier continuous software force register (AQCSFRC) is shown in [Figure 15-81](#) and described in [Table 15-73](#).

**Figure 15-81. Action-Qualifier Continuous Software Force Register (AQCSFRC)**

15	4	3	2	1	0
Reserved				CSFB	CSFA
R-0				R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-73. Action-Qualifier Continuous Software Force Register (AQCSFRC) Field Descriptions**

Bits	Name	Value	Description
15-4	Reserved	0	Reserved
3-2	CSFB	0-3h	<p>Continuous Software Force on Output B</p> <p>In immediate mode, a continuous force takes effect on the next TBCLK edge.</p> <p>In shadow mode, a continuous force takes effect on the next TBCLK edge after a shadow load into the active register. To configure shadow mode, use AQSFRC[RLDCSF].</p> <p>0 Forcing disabled, that is, has no effect</p> <p>1h Forces a continuous low on output B</p> <p>2h Forces a continuous high on output B</p> <p>3h Software forcing is disabled and has no effect</p>
1-0	CSFA	0-3h	<p>Continuous Software Force on Output A</p> <p>In immediate mode, a continuous force takes effect on the next TBCLK edge.</p> <p>In shadow mode, a continuous force takes effect on the next TBCLK edge after a shadow load into the active register.</p> <p>0 Forcing disabled, that is, has no effect</p> <p>1h Forces a continuous low on output A</p> <p>2h Forces a continuous high on output A</p> <p>3h Software forcing is disabled and has no effect</p>

#### 15.2.4.4 Dead-Band Generator Submodule Registers

[Table 15-74](#) lists the memory-mapped registers for the dead-band generator submodule. All other register offset addresses not listed in [Table 15-74](#) should be considered as reserved locations and the register contents should not be modified.

**Table 15-74. Dead-Band Generator Submodule Registers**

Offset	Acronym	Register Description	Section
1Eh	DBCTL	Dead-Band Generator Control Register	<a href="#">Section 15.2.4.4.1</a>
20h	DBRED	Dead-Band Generator Rising Edge Delay Register	<a href="#">Section 15.2.4.4.2</a>
22h	DBFED	Dead-Band Generator Falling Edge Delay Register	<a href="#">Section 15.2.4.4.3</a>

### 15.2.4.4.1 Dead-Band Generator Control Register (DBCTL)

The dead-band generator control register (DBCTL) is shown in [Figure 15-82](#) and described in [Table 15-75](#).

**Figure 15-82. Dead-Band Generator Control Register (DBCTL)**

15	6	5	4	3	2	1	0
Reserved				IN_MODE	POLSEL	OUT_MODE	
R-0				R/W-0	R/W-0	R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-75. Dead-Band Generator Control Register (DBCTL) Field Descriptions**

Bits	Name	Value	Description
15-6	Reserved	0	Reserved
5-4	IN_MODE	0-3h	<p>Dead Band Input Mode Control. Bit 5 controls the S5 switch and bit 4 controls the S4 switch shown in <a href="#">Figure 15-34</a>. This allows you to select the input source to the falling-edge and rising-edge delay. To produce classical dead-band waveforms, the default is EPWMxA In is the source for both falling and rising-edge delays.</p> <p>0 EPWMxA In (from the action-qualifier) is the source for both falling-edge and rising-edge delay.</p> <p>1h EPWMxB In (from the action-qualifier) is the source for rising-edge delayed signal.</p> <p>EPWMxA In (from the action-qualifier) is the source for falling-edge delayed signal.</p> <p>2h EPWMxA In (from the action-qualifier) is the source for rising-edge delayed signal.</p> <p>EPWMxB In (from the action-qualifier) is the source for falling-edge delayed signal.</p> <p>3h EPWMxB In (from the action-qualifier) is the source for both rising-edge delay and falling-edge delayed signal.</p>
3-2	POLSEL	0-3h	<p>Polarity Select Control. Bit 3 controls the S3 switch and bit 2 controls the S2 switch shown in <a href="#">Figure 15-34</a>. This allows you to selectively invert one of the delayed signals before it is sent out of the dead-band submodule.</p> <p>The following descriptions correspond to classical upper/lower switch control as found in one leg of a digital motor control inverter.</p> <p>These assume that DBCTL[OUT_MODE] = 1,1 and DBCTL[IN_MODE] = 0,0. Other enhanced modes are also possible, but not regarded as typical usage modes.</p> <p>0 Active high (AH) mode. Neither EPWMxA nor EPWMxB is inverted (default).</p> <p>1h Active low complementary (ALC) mode. EPWMxA is inverted.</p> <p>2h Active high complementary (AHC). EPWMxB is inverted.</p> <p>3h Active low (AL) mode. Both EPWMxA and EPWMxB are inverted.</p>
1-0	OUT_MODE	0-3h	<p>Dead-band Output Mode Control. Bit 1 controls the S1 switch and bit 0 controls the S0 switch shown in <a href="#">Figure 15-34</a>. This allows you to selectively enable or bypass the dead-band generation for the falling-edge and rising-edge delay.</p> <p>0 Dead-band generation is bypassed for both output signals. In this mode, both the EPWMxA and EPWMxB output signals from the action-qualifier are passed directly to the PWM-chopper submodule. In this mode, the POLSEL and IN_MODE bits have no effect.</p> <p>1h Disable rising-edge delay. The EPWMxA signal from the action-qualifier is passed straight through to the EPWMxA input of the PWM-chopper submodule. The falling-edge delayed signal is seen on output EPWMxB. The input signal for the delay is determined by DBCTL[IN_MODE].</p> <p>2h Disable falling-edge delay. The EPWMxB signal from the action-qualifier is passed straight through to the EPWMxB input of the PWM-chopper submodule. The rising-edge delayed signal is seen on output EPWMxA. The input signal for the delay is determined by DBCTL[IN_MODE].</p> <p>3h Dead-band is fully enabled for both rising-edge delay on output EPWMxA and falling-edge delay on output EPWMxB. The input signal for the delay is determined by DBCTL[IN_MODE].</p>

#### 15.2.4.4.2 Dead-Band Generator Rising Edge Delay Register (DBRED)

The dead-band generator rising edge delay register (DBRED) is shown in [Figure 15-83](#) and described in [Table 15-76](#).

**Figure 15-83. Dead-Band Generator Rising Edge Delay Register (DBRED)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-76. Dead-Band Generator Rising Edge Delay Register (DBRED) Field Descriptions**

Bits	Name	Value	Description
15-10	Reserved	0	Reserved
9-0	DEL	0-3FFh	Rising Edge Delay Count. 10-bit counter.

#### 15.2.4.4.3 Dead-Band Generator Falling Edge Delay Register (DBFED)

The dead-band generator falling edge delay register (DBFED) is shown in [Figure 15-84](#) and described in [Table 15-77](#).

**Figure 15-84. Dead-Band Generator Falling Edge Delay Register (DBFED)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-77. Dead-Band Generator Falling Edge Delay Register (DBFED) Field Descriptions**

Bits	Name	Value	Description
15-10	Reserved	0	Reserved
9-0	DEL	0-3FFh	Falling Edge Delay Count. 10-bit counter

### 15.2.4.5 Trip-Zone Submodule Registers

Table 15-78 lists the memory-mapped registers for the trip-zone submodule. All other register offset addresses not listed in Table 15-78 should be considered as reserved locations and the register contents should not be modified.

**Table 15-78. Trip-Zone Submodule Registers**

Offset	Acronym	Register Description	Section
24h	TZSEL	Trip-Zone Select Register	<a href="#">Section 15.2.4.5.1</a>
28h	TZCTL	Trip-Zone Control Register	<a href="#">Section 15.2.4.5.2</a>
2Ah	TZEINT	Trip-Zone Enable Interrupt Register	<a href="#">Section 15.2.4.5.3</a>
2Ch	TZFLG	Trip-Zone Flag Register	<a href="#">Section 15.2.4.5.4</a>
2Eh	TZCLR	Trip-Zone Clear Register	<a href="#">Section 15.2.4.5.5</a>
30h	TZFRC	Trip-Zone Force Register	<a href="#">Section 15.2.4.5.6</a>

#### 15.2.4.5.1 Trip-Zone Select Register (TZSEL)

The trip-zone select register (TZSEL) is shown in Figure 15-85 and described in Table 15-79.

**Figure 15-85. Trip-Zone Select Register (TZSEL)**

15	9	8	7	1	0
Reserved/OSHT $n$ <sup>(1)</sup>		OSHT1	Reserved/CBC $n$ <sup>(1)</sup>		CBC1
R/W-0		R/W-0	R/W-0		R/W-0

LEGEND: R/W = Read/Write; -n = value after reset

<sup>(1)</sup> Number of register bits depends on how many trip-zone pins are available in the device. See your device-specific data manual.

**Table 15-79. Trip-Zone Submodule Select Register (TZSEL) Field Descriptions**

Bits	Name	Value	Description
15-8	OSHT $n$		Trip-zone $n$ ( $\overline{TZn}$ ) select. One-Shot (OSHT) trip-zone enable/disable. When any of the enabled pins go low, a one-shot trip event occurs for this ePWM module. When the event occurs, the action defined in the TZCTL register ( <a href="#">Section 15.2.4.5.2</a> ) is taken on the EPWMxA and EPWMxB outputs. The one-shot trip condition remains latched until you clear the condition via the TZCLR register ( <a href="#">Section 15.2.4.5.5</a> ).
		0	Disable $\overline{TZn}$ as a one-shot trip source for this ePWM module.
		1	Enable $\overline{TZn}$ as a one-shot trip source for this ePWM module.
7-0	CBC $n$		Trip-zone $n$ ( $\overline{TZn}$ ) select. Cycle-by-Cycle (CBC) trip-zone enable/disable. When any of the enabled pins go low, a cycle-by-cycle trip event occurs for this ePWM module. When the event occurs, the action defined in the TZCTL register ( <a href="#">Section 15.2.4.5.2</a> ) is taken on the EPWMxA and EPWMxB outputs. A cycle-by-cycle trip condition is automatically cleared when the time-base counter reaches zero.
		0	Disable $\overline{TZn}$ as a CBC trip source for this ePWM module.
		1	Enable $\overline{TZn}$ as a CBC trip source for this ePWM module.

### 15.2.4.5.2 Trip-Zone Control Register (TZCTL)

The trip-zone control register (TZCTL) is shown in [Figure 15-86](#) and described in [Table 15-80](#).

**Figure 15-86. Trip-Zone Control Register (TZCTL)**

15	Reserved	4	3	2	1	0
R-0			TZB	TZA		
R-0			R/W-0	R/W-0		R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-80. Trip-Zone Control Register (TZCTL) Field Descriptions**

Bits	Name	Value	Description
15-4	Reserved	0	Reserved
3-2	TZB	0-3h	When a trip event occurs the following action is taken on output EPWMxB. Which trip-zone pins can cause an event is defined in the TZSEL register ( <a href="#">Section 15.2.4.5.1</a> ).
		0	High impedance (EPWMxB = High-impedance state)
		1h	Force EPWMxB to a high state
		2h	Force EPWMxB to a low state
		3h	Do nothing, no action is taken on EPWMxB.
1-0	TZA	0-3h	When a trip event occurs the following action is taken on output EPWMxA. Which trip-zone pins can cause an event is defined in the TZSEL register ( <a href="#">Section 15.2.4.5.1</a> ).
		0	High impedance (EPWMxA = High-impedance state)
		1h	Force EPWMxA to a high state
		2h	Force EPWMxA to a low state
		3h	Do nothing, no action is taken on EPWMxA.

### 15.2.4.5.3 Trip-Zone Enable Interrupt Register (TZEINT)

The trip-zone enable interrupt register (TZEINT) is shown in [Figure 15-87](#) and described in [Table 15-81](#).

**Figure 15-87. Trip-Zone Enable Interrupt Register (TZEINT)**

15	Reserved	3	2	1	0
R-0			OST	CBC	Rsvd
R-0			R/W-0	R/W-0	R-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-81. Trip-Zone Enable Interrupt Register (TZEINT) Field Descriptions**

Bits	Name	Value	Description
15-3	Reserved	0	Reserved
2	OST		Trip-zone One-Shot Interrupt Enable
		0	Disable one-shot interrupt generation
		1	Enable Interrupt generation; a one-shot trip event will cause a EPWMxTZINT interrupt.
1	CBC		Trip-zone Cycle-by-Cycle Interrupt Enable
		0	Disable cycle-by-cycle interrupt generation.
		1	Enable interrupt generation; a cycle-by-cycle trip event will cause an EPWMxTZINT interrupt.
0	Reserved	0	Reserved

#### 15.2.4.5.4 Trip-Zone Flag Register (TZFLG)

The trip-zone flag register (TZFLG) is shown in [Figure 15-88](#) and described in [Table 15-82](#).

**Figure 15-88. Trip-Zone Flag Register (TZFLG)**

15	Reserved	3	2	1	0
		OST	CBC	INT	
	R-0		R-0	R-0	R-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-82. Trip-Zone Flag Register (TZFLG) Field Descriptions**

Bits	Name	Value	Description
15-3	Reserved	0	Reserved
2	OST	0 1	Latched Status Flag for A One-Shot Trip Event. 0 No one-shot trip event has occurred. 1 Indicates a trip event has occurred on a pin selected as a one-shot trip source. This bit is cleared by writing the appropriate value to the TZCLR register ( <a href="#">Section 15.2.4.5.5</a> ).
1	CBC	0 1	Latched Status Flag for Cycle-By-Cycle Trip Event 0 No cycle-by-cycle trip event has occurred. 1 Indicates a trip event has occurred on a pin selected as a cycle-by-cycle trip source. The TZFLG[CBC] bit will remain set until it is manually cleared by the user. If the cycle-by-cycle trip event is still present when the CBC bit is cleared, then CBC will be immediately set again. The specified condition on the pins is automatically cleared when the ePWM time-base counter reaches zero (TBCNT = 0000h) if the trip condition is no longer present. The condition on the pins is only cleared when the TBCNT = 0000h no matter where in the cycle the CBC flag is cleared. This bit is cleared by writing the appropriate value to the TZCLR register ( <a href="#">Section 15.2.4.5.5</a> ).
0	INT	0 1	Latched Trip Interrupt Status Flag 0 Indicates no interrupt has been generated. 1 Indicates an EPWMxTZINT interrupt was generated because of a trip condition. No further EPWMxTZINT interrupts will be generated until this flag is cleared. If the interrupt flag is cleared when either CBC or OST is set, then another interrupt pulse will be generated. Clearing all flag bits will prevent further interrupts. This bit is cleared by writing the appropriate value to the TZCLR register ( <a href="#">Section 15.2.4.5.5</a> ).

### 15.2.4.5.5 Trip-Zone Clear Register (TZCLR)

The trip-zone clear register (TZCLR) is shown in [Figure 15-89](#) and described in [Table 15-83](#).

**Figure 15-89. Trip-Zone Clear Register (TZCLR)**

15	Reserved	3	2	1	0
			OST	CBC	INT
	R-0		R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-83. Trip-Zone Clear Register (TZCLR) Field Descriptions**

Bits	Name	Value	Description
15-3	Reserved	0	Reserved
2	OST	0	Clear Flag for One-Shot Trip (OST) Latch Has no effect. Always reads back a 0.
		1	Clears this Trip (set) condition.
1	CBC	0	Clear Flag for Cycle-By-Cycle (CBC) Trip Latch Has no effect. Always reads back a 0.
		1	Clears this Trip (set) condition.
0	INT	0	Global Interrupt Clear Flag Has no effect. Always reads back a 0.
		1	Clears the trip-interrupt flag for this ePWM module (TZFLG[INT]). <b>NOTE:</b> No further EPWMxTZINT interrupts will be generated until the flag is cleared. If the TZFLG[INT] bit is cleared and any of the other flag bits are set, then another interrupt pulse will be generated. Clearing all flag bits will prevent further interrupts.

### 15.2.4.5.6 Trip-Zone Force Register (TZFRC)

The trip-zone force register (TZFRC) is shown in [Figure 15-90](#) and described in [Table 15-84](#).

**Figure 15-90. Trip-Zone Force Register (TZFRC)**

15	Reserved	3	2	1	0
			OST	CBC	Rsvd
	R-0		R/W-0	R/W-0	R-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-84. Trip-Zone Force Register (TZFRC) Field Descriptions**

Bits	Name	Value	Description
15-3	Reserved	0	Reserved
2	OST	0	Force a One-Shot Trip Event via Software Writing of 0 is ignored. Always reads back a 0.
		1	Forces a one-shot trip event and sets the TZFLG[OST] bit.
1	CBC	0	Force a Cycle-by-Cycle Trip Event via Software Writing of 0 is ignored. Always reads back a 0.
		1	Forces a cycle-by-cycle trip event and sets the TZFLG[CBC] bit.
0	Reserved	0	Reserved

### 15.2.4.6 Event-Trigger Submodule Registers

Table 15-85 lists the memory-mapped registers for the event-trigger submodule. See your device-specific data manual for the memory address of these registers. All other register offset addresses not listed in Table 15-85 should be considered as reserved locations and the register contents should not be modified.

**Table 15-85. Event-Trigger Submodule Registers**

Offset	Acronym	Register Description	Section
32h	ETSEL	Event-Trigger Selection Register	<a href="#">Section 15.2.4.6.1</a>
34h	ETPS	Event-Trigger Prescale Register	<a href="#">Section 15.2.4.6.2</a>
36h	ETFLG	Event-Trigger Flag Register	<a href="#">Section 15.2.4.6.3</a>
38h	ETCLR	Event-Trigger Clear Register	<a href="#">Section 15.2.4.6.4</a>
3Ah	ETFRC	Event-Trigger Force Register	<a href="#">Section 15.2.4.6.5</a>

#### 15.2.4.6.1 Event-Trigger Selection Register (ETSEL)

The event-trigger selection register (ETSEL) is shown in Figure 15-91 and described in Table 15-86.

**Figure 15-91. Event-Trigger Selection Register (ETSEL)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-86. Event-Trigger Selection Register (ETSEL) Field Descriptions**

Bits	Name	Value	Description
15-4	Reserved	0	Reserved
3	INTEN	0 1	Enable ePWM Interrupt (EPWMx_INT) Generation Disable EPWMx_INT generation Enable EPWMx_INT generation
2-0	INTSEL	0-7h 0 1h 2h 3h 4h 5h 6h 7h	ePWM Interrupt (EPWMx_INT) Selection Options Reserved Enable event time-base counter equal to zero. (TBCNT = 0000h) Enable event time-base counter equal to period (TBCNT = TBPRD) Reserved Enable event time-base counter equal to CMPA when the timer is incrementing. Enable event time-base counter equal to CMPA when the timer is decrementing. Enable event: time-base counter equal to CMPB when the timer is incrementing. Enable event: time-base counter equal to CMPB when the timer is decrementing.

### 15.2.4.6.2 Event-Trigger Prescale Register (ETPS)

The event-trigger prescale register (ETPS) is shown in [Figure 15-92](#) and described in [Table 15-87](#).

**Figure 15-92. Event-Trigger Prescale Register (ETPS)**

15	4	3	2	1	0
Reserved				INTCNT	INTPRD
R-0				R-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-87. Event-Trigger Prescale Register (ETPS) Field Descriptions**

Bits	Name	Value	Description
15-4	Reserved	0	Reserved
3-2	INTCNT	0-3h	ePWM Interrupt Event (EPWMx_INT) Counter Register. These bits indicate how many selected ETSEL[INTSEL] events have occurred. These bits are automatically cleared when an interrupt pulse is generated. If interrupts are disabled, ETSEL[INT] = 0 or the interrupt flag is set, ETFLG[INT] = 1, the counter will stop counting events when it reaches the period value ETPS[INTCNT] = ETPS[INTPRD].
		0	No events have occurred.
		1h	1 event has occurred.
		2h	2 events have occurred.
		3h	3 events have occurred.
1-0	INTPRD	0-3h	ePWM Interrupt (EPWMx_INT) Period Select. These bits determine how many selected ETSEL[INTSEL] events need to occur before an interrupt is generated. To be generated, the interrupt must be enabled (ETSEL[INT] = 1). If the interrupt status flag is set from a previous interrupt (ETFLG[INT] = 1) then no interrupt will be generated until the flag is cleared via the ETCLR[INT] bit. This allows for one interrupt to be pending while another is still being serviced. Once the interrupt is generated, the ETPS[INTCNT] bits will automatically be cleared.  Writing a INTPRD value that is the same as the current counter value will trigger an interrupt if it is enabled and the status flag is clear.  Writing a INTPRD value that is less than the current counter value will result in an undefined state.  If a counter event occurs at the same instant as a new zero or non-zero INTPRD value is written, the counter is incremented.
		0	Disable the interrupt event counter. No interrupt will be generated and ETFRC[INT] is ignored.
		1h	Generate an interrupt on the first event INTCNT = 01 (first event)
		2h	Generate interrupt on ETPS[INTCNT] = 1,0 (second event)
		3h	Generate interrupt on ETPS[INTCNT] = 1,1 (third event)

### 15.2.4.6.3 Event-Trigger Flag Register (ETFLG)

The event-trigger flag register (ETFLG) is shown in [Figure 15-93](#) and described in [Table 15-88](#).

**Figure 15-93. Event-Trigger Flag Register (ETFLG)**

15	Reserved	1	0
R-0		INT R-0	

LEGEND: R = Read only; -n = value after reset

**Table 15-88. Event-Trigger Flag Register (ETFLG) Field Descriptions**

Bits	Name	Value	Description
15-1	Reserved	0	Reserved
0	INT	0	Latched ePWM Interrupt (EPWMx_INT) Status Flag Indicates no event occurred
		1	Indicates that an ePWMx interrupt (EPWMx_INT) was generated. No further interrupts will be generated until the flag bit is cleared. Up to one interrupt can be pending while the ETFLG[INT] bit is still set. If an interrupt is pending, it will not be generated until after the ETFLG[INT] bit is cleared. Refer to <a href="#">Figure 15-47</a> .

### 15.2.4.6.4 Event-Trigger Clear Register (ETCLR)

The event-trigger clear register (ETCLR) is shown in [Figure 15-94](#) and described in [Table 15-89](#).

**Figure 15-94. Event-Trigger Clear Register (ETCLR)**

15	Reserved	1	0
R-0		INT R-0	

LEGEND: R = Read only; -n = value after reset

**Table 15-89. Event-Trigger Clear Register (ETCLR) Field Descriptions**

Bits	Name	Value	Description
15-1	Reserved	0	Reserved
0	INT	0	ePWM Interrupt (EPWMx_INT) Flag Clear Bit Writing a 0 has no effect. Always reads back a 0.
		1	Clears the ETFLG[INT] flag bit and enable further interrupts pulses to be generated. Note that interrupts can also used as DMA events, and this will also enable further DMA events to be generated.

### 15.2.4.6.5 Event-Trigger Force Register (ETFRC)

The event-trigger force register (ETFRC) is shown in [Figure 15-95](#) and described in [Table 15-90](#).

**Figure 15-95. Event-Trigger Force Register (ETFRC)**

LEGEND: R = Read only; -n = value after reset

**Table 15-90. Event-Trigger Force Register (ETFRC) Field Descriptions**

Bits	Name	Value	Description
15-1	Reserved	0	Reserved
0	INT	0	INT Force Bit. The interrupt will only be generated if the event is enabled in the ETSEL register. The INT flag bit will be set regardless.
		0	Writing 0 to this bit will be ignored. Always reads back a 0.
		1	Generates an interrupt on $\overline{\text{EPWMxINT}}$ and set the INT flag bit. This bit is used for test purposes.

### 15.2.4.7 PWM-Chopper Submodule Register

The PWM-chopper control register (PCCTL) is shown in [Figure 15-96](#) and described in [Table 15-91](#).

**Figure 15-96. PWM-Chopper Control Register (PCCTL)**

15	11	10	8	7	5	4	1	0
Reserved		CHPDUTY		CHPFREQ		OSHTWTH		CHPEN
R-0		R/W-0		R/W-0		R/W-0		R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-91. PWM-Chopper Control Register (PCCTL) Bit Descriptions**

Bits	Name	Value	Description
15-11	Reserved	0	Reserved
10-8	CHPDUTY	0-7h	Chopping Clock Duty Cycle
		0	Duty = 1/8 (12.5%)
		1h	Duty = 2/8 (25.0%)
		2h	Duty = 3/8 (37.5%)
		3h	Duty = 4/8 (50.0%)
		4h	Duty = 5/8 (62.5%)
		5h	Duty = 6/8 (75.0%)
		6h	Duty = 7/8 (87.5%)
7h	Reserved		
7-5	CHPFREQ	0-7h	Chopping Clock Frequency
		0	Divide by 1 (no prescale)
		1h	Divide by 2
		2h	Divide by 3
		3h-7h	Divide by 4 to divide by 8
4-1	OSHTWTH	0-Fh	One-Shot Pulse Width
		0	1 × SYSCLKOUT/8 wide
		1h	2 × SYSCLKOUT/8 wide
		2h	3 × SYSCLKOUT/8 wide
3h-Fh	4 × SYSCLKOUT/8 wide to 16 × SYSCLKOUT/8 wide		
0	CHPEN		PWM-chopping Enable
		0	Disable (bypass) PWM chopping function
		1	Enable chopping function

### 15.2.4.8 High-Resolution PWM Submodule Registers

[Table 15-92](#) lists the memory-mapped registers for the high-resolution PWM submodule. All other register offset addresses not listed in [Table 15-92](#) should be considered as reserved locations and the register contents should not be modified.

**Table 15-92. High-Resolution PWM Submodule Registers**

Offset	Acronym	Register Description	Section
4h	TBPHSHR	Time-Base Phase High-Resolution Register	<a href="#">Section 15.2.4.8.1</a>
10h	CMPAHR	Counter-Compare A High-Resolution Register	<a href="#">Section 15.2.4.8.2</a>
40h	HRCTL	HRPWM Control Register	<a href="#">Section 15.2.4.8.3</a>

### 15.2.4.8.1 Time-Base Phase High-Resolution Register (TBPHSHR)

The time-base phase high-resolution register (TBPHSHR) is shown in [Figure 15-97](#) and described in [Table 15-93](#).

**Figure 15-97. Time-Base Phase High-Resolution Register (TBPHSHR)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-93. Time-Base Phase High-Resolution Register (TBPHSHR) Field Descriptions**

Bit	Field	Value	Description
15-8	TBPHSH	0-FFh	Time-base phase high-resolution bits
7-0	Reserved	0	Reserved

### 15.2.4.8.2 Counter-Compare A High-Resolution Register (CMPAHR)

The counter-compare A high-resolution register (CMPAHR) is shown in [Figure 15-98](#) and described in [Table 15-94](#).

**Figure 15-98. Counter-Compare A High-Resolution Register (CMPAHR)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-94. Counter-Compare A High-Resolution Register (CMPAHR) Field Descriptions**

Bit	Field	Value	Description
15-8	CMPAHR	1-FFh	Compare A High-Resolution register bits for MEP step control. A minimum value of 1h is needed to enable HRPWM capabilities. Valid MEP range of operation 1-255h.
7-0	Reserved	0	Reserved

### 15.2.4.8.3 HRPWM Control Register (HRCTL)

The HRPWM control register (HRCTL) is shown in [Figure 15-99](#) and described in [Table 15-95](#).

**Figure 15-99. HRPWM Control Register (HRCTL)**

15	4	3	2	1	0
Reserved		PULSESEL	DELBUSSEL	DELMODE	
R-0		R/W-0	R/W-0	R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-95. HRPWM Control Register (HRCTL) Field Descriptions**

Bit	Field	Value	Description
15-4	Reserved	0	Reserved
3	PULSESEL	0 1	Pulse select bits. Selects which pulse to use for timing events in the HRPWM module: Select CNT_zero pulse Select PRD_eq pulse Note: The user needs to select the pulse to match the selection in the EPWM module. If TBPMSHR bus is selected, then CNT_zero pulse should be used. If COMPAHR bus is selected, then it should match the bit setting of the CMPCTL[LOADMODE] bits in the EPWM module as follows: 0 CNT_zero pulse 1h PRD_eq pulse 2h CNT_zero or PRD_eq (should not use with HRPWM) 3h No loads (should not use with HRPWM)
2	DELBUSSEL	0 1	Delay Bus Select Bit: Selects which bus is used to select the delay for the PWM pulse: Select COMPAHR(8) bus from compare module of EPWM (default on reset). Select TBPMSHR(8) bus from time base module.
1-0	DELMODE	0-3h 0 1h 2h 3h	Delay Mode Bits: Selects which edge of the PWM pulse the delay is inserted: No delay inserted (default on reset) Delay inserted rising edge Delay inserted falling edge Delay inserted on both edges Note: When DELMODE = 0,0, the HRCALM[CALMODE] bits are ignored and the delay line is in by-pass mode. Additionally, DLYIN is connected to CALIN and a continuous low value is fed to the delay line to minimize activity in the module.

## 15.3 Enhanced Capture (eCAP) Module

### 15.3.1 Introduction

#### 15.3.1.1 Purpose of the Peripheral

Uses for eCAP include:

- Sample rate measurements of audio inputs
- Speed measurements of rotating machinery (for example, toothed sprockets sensed via Hall sensors)
- Elapsed time measurements between position sensor pulses
- Period and duty cycle measurements of pulse train signals
- Decoding current or voltage amplitude derived from duty cycle encoded current/voltage sensors

#### 15.3.1.2 Features

The eCAP module includes the following features:

- 32-bit time base counter
- 4-event time-stamp registers (each 32 bits)
- Edge polarity selection for up to four sequenced time-stamp capture events
- Interrupt on either of the four events
- Single shot capture of up to four event time-stamps
- Continuous mode capture of time-stamps in a four-deep circular buffer
- Absolute time-stamp capture
- Difference (Delta) mode time-stamp capture
- All above resources dedicated to a single input pin
- When not used in capture mode, the ECAP module can be configured as a single channel PWM output

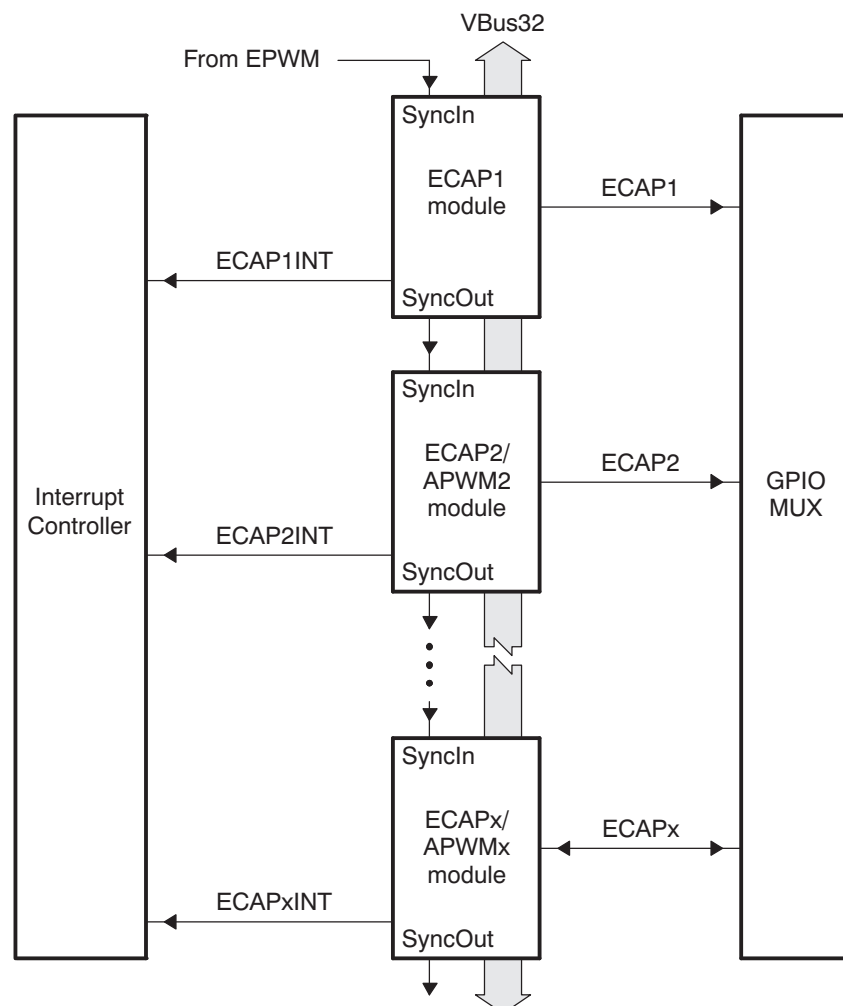

### 15.3.2 Functional Description

The eCAP module represents one complete capture channel that can be instantiated multiple times depending on the target device. In the context of this guide, one eCAP channel has the following independent key resources:

- Dedicated input capture pin
- 32-bit time base counter
- 4 × 32-bit time-stamp capture registers (CAP1-CAP4)
- 4-stage sequencer (Modulo4 counter) that is synchronized to external events, ECAP pin rising/falling edges.
- Independent edge polarity (rising/falling edge) selection for all 4 events
- Input capture signal prescaling (from 2-62)
- One-shot compare register (2 bits) to freeze captures after 1 to 4 time-stamp events
- Control for continuous time-stamp captures using a 4-deep circular buffer (CAP1-CAP4) scheme
- Interrupt capabilities on any of the 4 capture events

Multiple identical eCAP modules can be contained in a system as shown in [Figure 15-100](#). The number of modules is device-dependent and is based on target application needs. In this chapter, the letter x within a signal or module name is used to indicate a generic eCAP instance on a device.

**Figure 15-100. Multiple eCAP Modules**

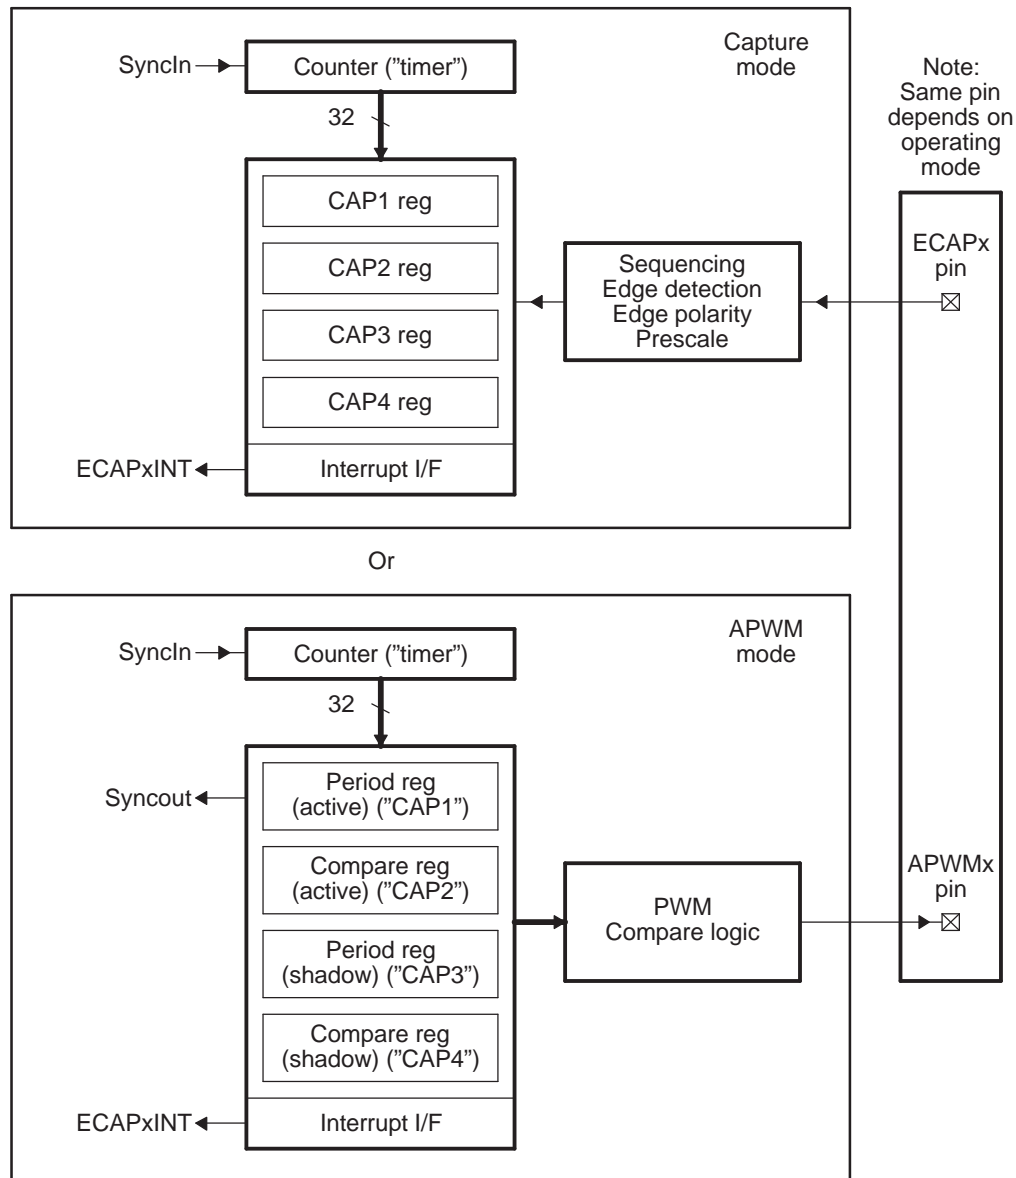

### 15.3.2.1 Capture and APWM Operating Mode

You can use the eCAP module resources to implement a single-channel PWM generator (with 32 bit capabilities) when it is not being used for input captures. The counter operates in count-up mode, providing a time-base for asymmetrical pulse width modulation (PWM) waveforms. The CAP1 and CAP2 registers become the active period and compare registers, respectively, while CAP3 and CAP4 registers become the period and capture shadow registers, respectively. Figure 15-101 is a high-level view of both the capture and auxiliary pulse-width modulator (APWM) modes of operation.

**Figure 15-101. Capture and APWM Modes of Operation**

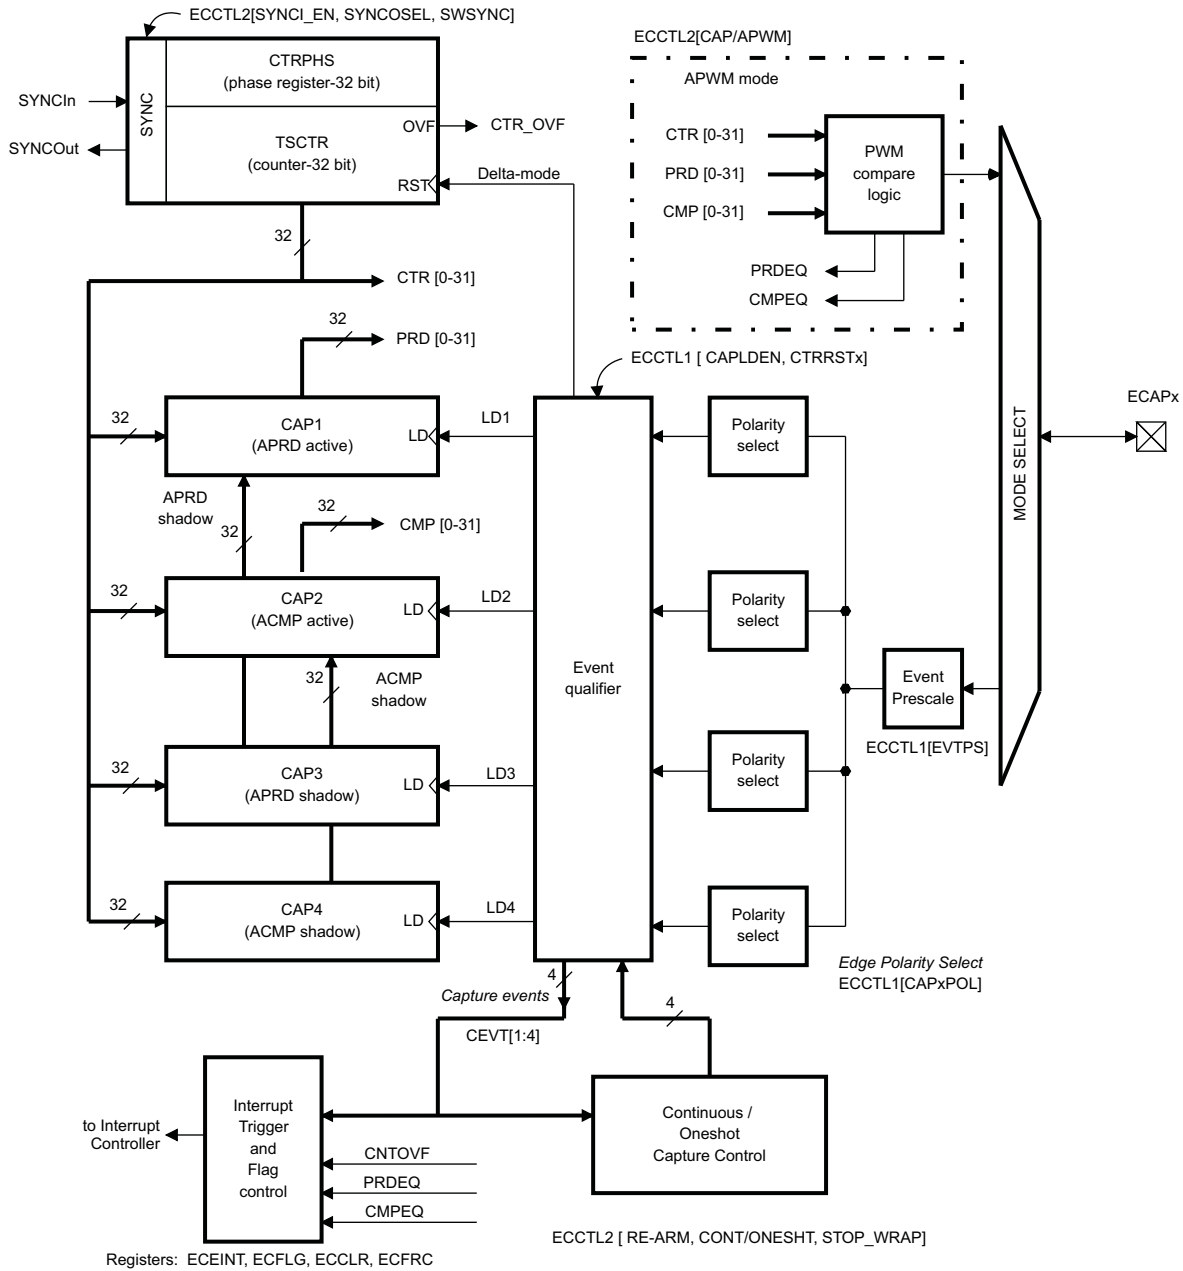

- (1) A single pin is shared between CAP and APWM functions. In capture mode, it is an input; in APWM mode, it is an output.
- (2) In APWM mode, writing any value to CAP1/CAP2 active registers also writes the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 invokes the shadow mode.

15.3.2.2 Capture Mode Description

Figure 15-102 shows the various components that implement the capture function.

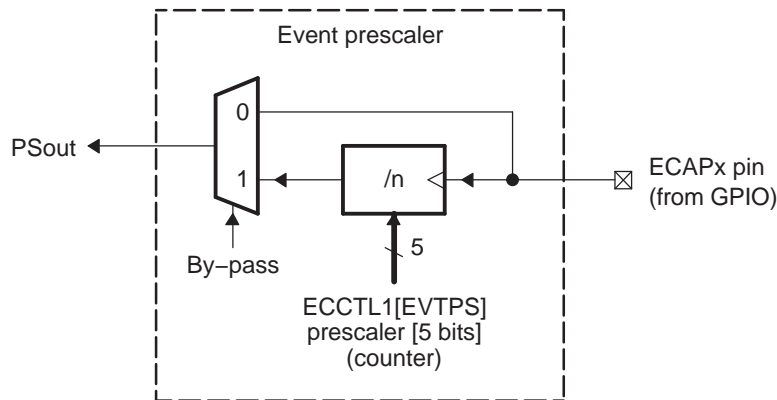

Figure 15-102. Capture Function Diagram

15.3.2.2.1 Event Prescaler

An input capture signal (pulse train) can be prescaled by  $N = 2-62$  (in multiples of 2) or can bypass the prescaler. This is useful when very high frequency signals are used as inputs. Figure 15-103 shows a functional diagram and Figure 15-104 shows the operation of the prescale function.

Figure 15-103. Event Prescaler Control

- (1) When a prescale value of 1 is chosen (ECCTL1[13:9] = 0000) the input capture signal by-passes the prescale logic completely.

Figure 15-104. Prescale Function Waveforms

### 15.3.2.2.2 Edge Polarity Select and Qualifier

- Four independent edge polarity (rising edge/falling edge) selection multiplexers are used, one for each capture event.
- Each edge (up to 4) is event qualified by the Modulo4 sequencer.
- The edge event is gated to its respective CAP $n$  register by the Mod4 counter. The CAP $n$  register is loaded on the falling edge.

### 15.3.2.2.3 Continuous/One-Shot Control

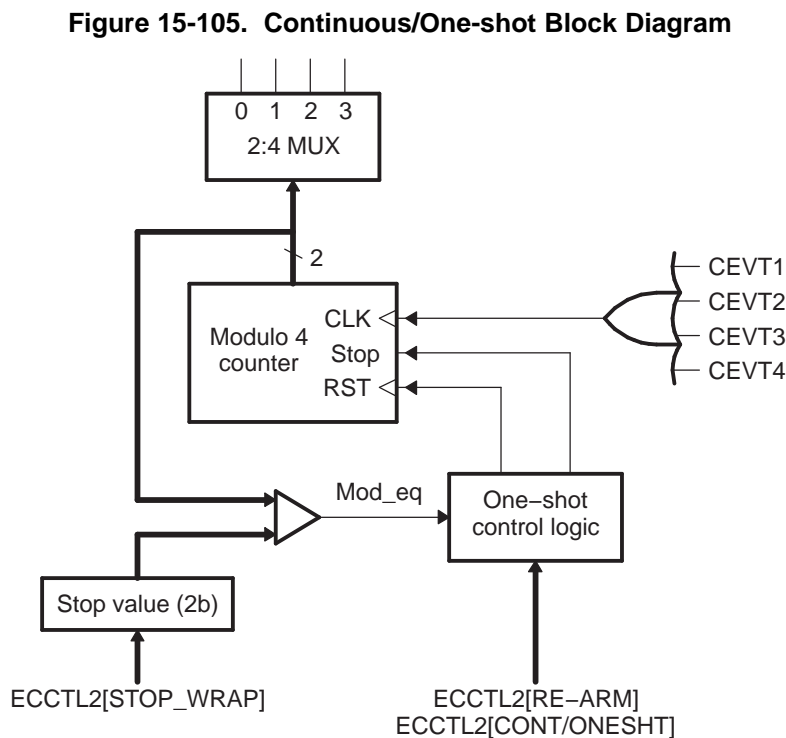

- The Mod4 (2 bit) counter is incremented via edge qualified events (CEVT1-CEVT4).
- The Mod4 counter continues counting (0->1->2->3->0) and wraps around unless stopped.
- A 2-bit stop register is used to compare the Mod4 counter output, and when equal stops the Mod4 counter and inhibits further loads of the CAP1-CAP4 registers. This occurs during one-shot operation.

The continuous/one-shot block (Figure 15-105) controls the start/stop and reset (zero) functions of the Mod4 counter via a mono-shot type of action that can be triggered by the stop-value comparator and re-armed via software control.

Once armed, the eCAP module waits for 1-4 (defined by stop-value) capture events before freezing both the Mod4 counter and contents of CAP1-4 registers (time-stamps).

Re-arming prepares the eCAP module for another capture sequence. Also re-arming clears (to zero) the Mod4 counter and permits loading of CAP1-4 registers again, providing the CAPLDEN bit is set.

In continuous mode, the Mod4 counter continues to run (0->1->2->3->0, the one-shot action is ignored, and capture values continue to be written to CAP1-4 in a circular buffer sequence.

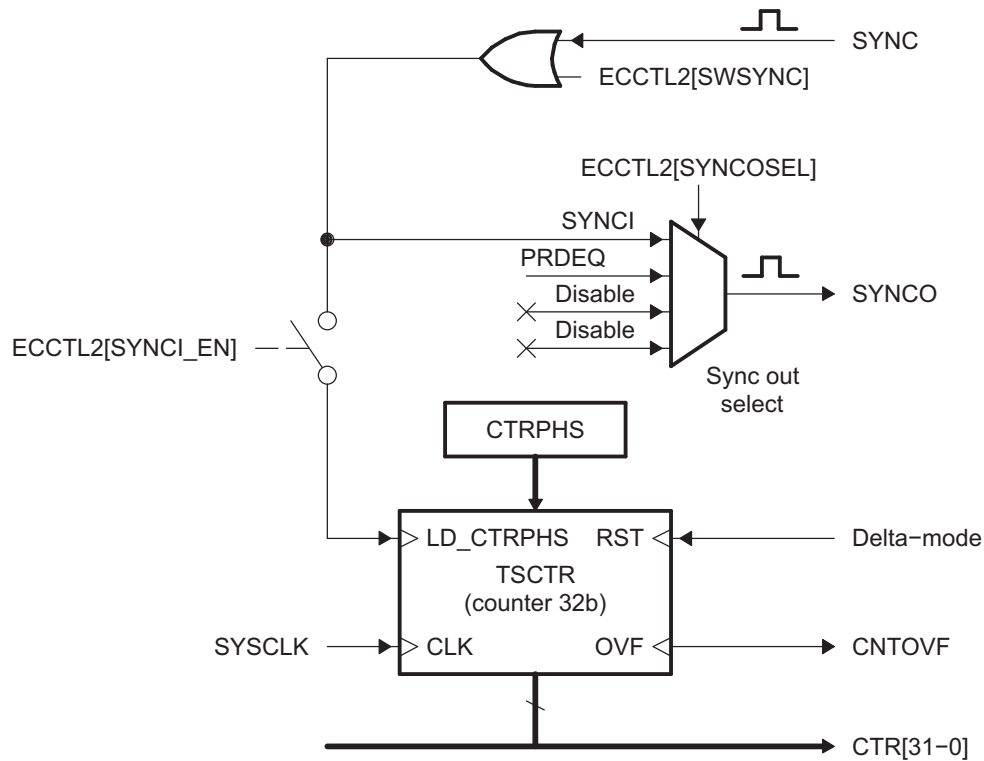

15.3.2.2.4 32-Bit Counter and Phase Control

This counter (Figure 15-106) provides the time-base for event captures, and is clocked via the system clock.

A phase register is provided to achieve synchronization with other counters, via a hardware and software forced sync. This is useful in APWM mode when a phase offset between modules is needed.

On any of the four event loads, an option to reset the 32-bit counter is given. This is useful for time difference capture. The 32-bit counter value is captured first, then it is reset to 0 by any of the LD1-LD4 signals.

Figure 15-106. Counter and Synchronization Block Diagram

### 15.3.2.2.5 CAP1-CAP4 Registers

These 32-bit registers are fed by the 32-bit counter timer bus, CTR[0-31] and are loaded (capture a time-stamp) when their respective LD inputs are strobed.

Loading of the capture registers can be inhibited via control bit CAPLDEN. During one-shot operation, this bit is cleared (loading is inhibited) automatically when a stop condition occurs, StopValue = Mod4.

CAP1 and CAP2 registers become the active period and compare registers, respectively, in APWM mode.

CAP3 and CAP4 registers become the respective shadow registers (APRD and ACMP) for CAP1 and CAP2 during APWM operation.

### 15.3.2.2.6 Interrupt Control

An Interrupt can be generated on capture events (CEVT1-CEVT4, CNTOVF) or APWM events (PRDEQ, CMPEQ). See [Figure 15-107](#).

A counter overflow event (FFFF FFFFh->0000 0000h) is also provided as an interrupt source (CNTOVF).

The capture events are edge and sequencer qualified (that is, ordered in time) by the polarity select and Mod4 gating, respectively.

One of these events can be selected as the interrupt source (from the eCAP<sub>n</sub> module) going to the interrupt controller.

Seven interrupt events (CEVT1, CEVT2, CEVT3, CEVT4, CNTOVF, PRDEQ, CMPEQ) can be generated. The interrupt enable register (ECEINT) is used to enable/disable individual interrupt event sources. The interrupt flag register (ECFLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT). An interrupt pulse is generated to the interrupt controller only if any of the interrupt events are enabled, the flag bit is 1, and the INT flag bit is 0. The interrupt service routine must clear the global interrupt flag bit and the serviced event via the interrupt clear register (ECCLR) before any other interrupt pulses are generated. You can force an interrupt event via the interrupt force register (ECFRC). This is useful for test purposes.

Note that the interrupts coming from the eCAP module are also used as DMA events. The interrupt registers should be used to enable and clear the current DMA event in order for the eCAP module to generate subsequent DMA events.

### 15.3.2.2.7 Shadow Load and Lockout Control

In capture mode, this logic inhibits (locks out) any shadow loading of CAP1 or CAP2 from APRD and ACMP registers, respectively.

In APWM mode, shadow loading is active and two choices are permitted:

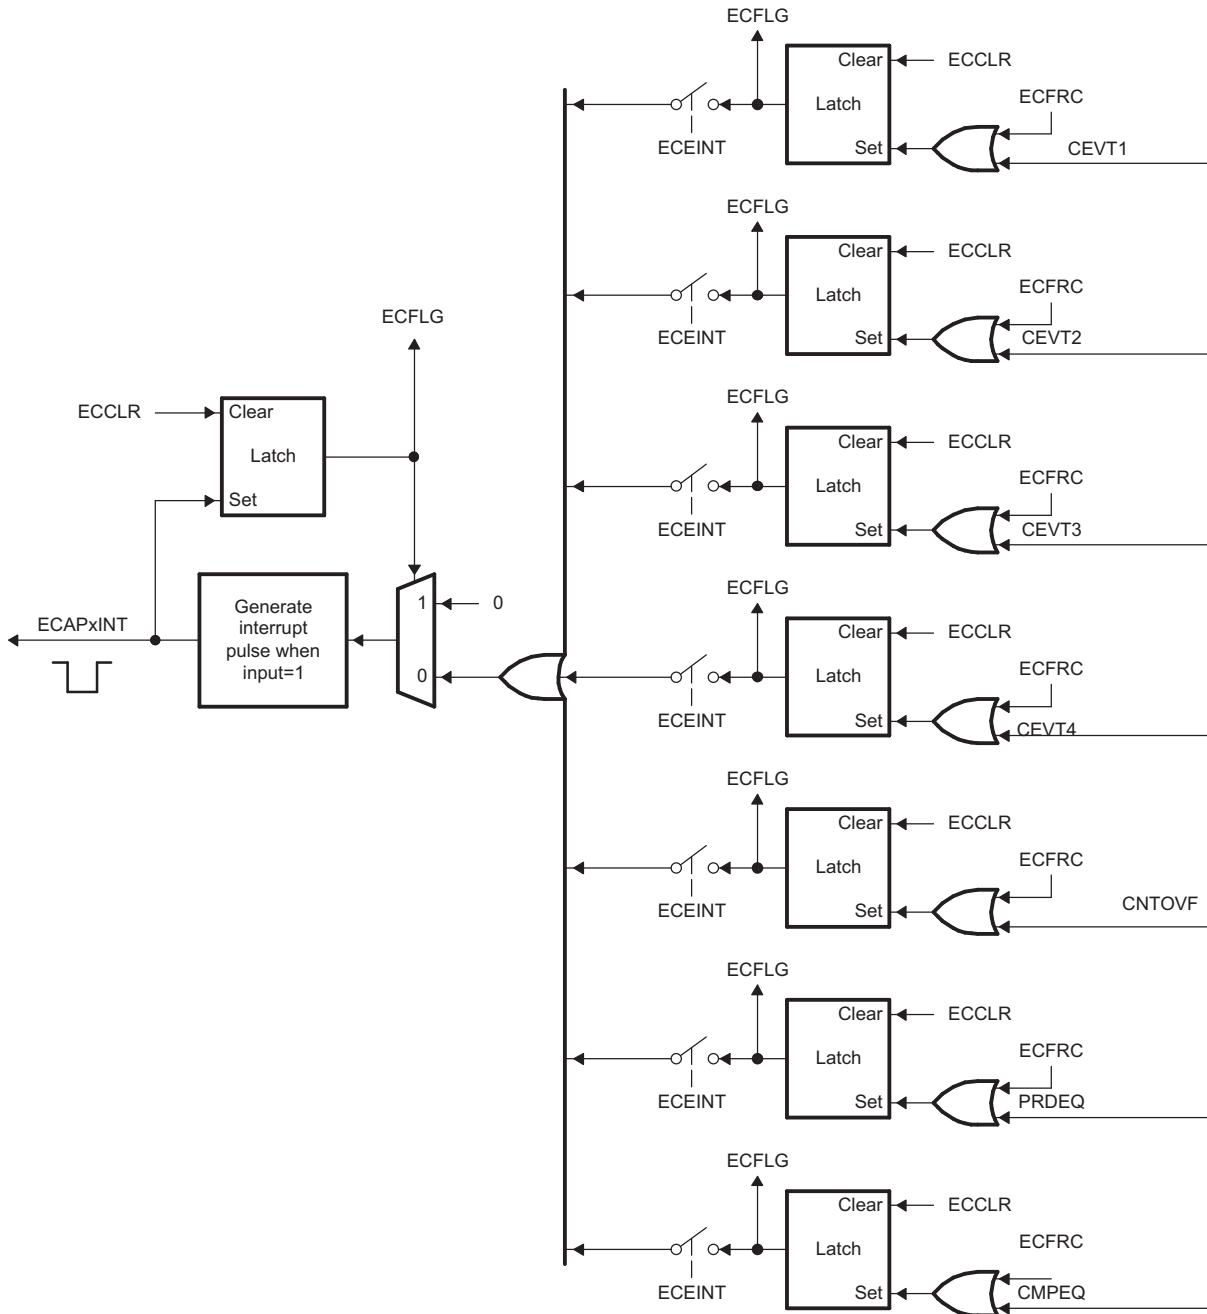

- Immediate - APRD or ACMP are transferred to CAP1 or CAP2 immediately upon writing a new value.
- On period equal, CTR[31:0] = PRD[31:0]

---

**NOTE:** The CEVT1, CEVT2, CEVT3, CEVT4 flags are only active in capture mode (ECCTL2[CAP/APWM == 0]). The PRDEQ, CMPEQ flags are only valid in APWM mode (ECCTL2[CAP/APWM == 1]). CNTOVF flag is valid in both modes.

---

Figure 15-107. Interrupts in eCAP Module

### 15.3.2.2.8 APWM Mode Operation

Main operating highlights of the APWM section:

- The time-stamp counter bus is made available for comparison via 2 digital (32-bit) comparators.
- When CAP1/2 registers are not used in capture mode, their contents can be used as Period and Compare values in APWM mode.
- Double buffering is achieved via shadow registers APRD and ACMP (CAP3/4). The shadow register contents are transferred over to CAP1/2 registers either immediately upon a write, or on a PRDEQ trigger.
- In APWM mode, writing to CAP1/CAP2 active registers will also write the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 will invoke the shadow mode.
- During initialization, you must write to the active registers for both period and compare. This automatically copies the initial values into the shadow values. For subsequent compare updates, during run-time, you only need to use the shadow registers.

**Figure 15-108. PWM Waveform Details Of APWM Mode Operation**

The behavior of APWM active-high mode (APWMPOL == 0) is:

CMP = 0x00000000, output low for duration of period (0% duty)  
 CMP = 0x00000001, output high 1 cycle  
 CMP = 0x00000002, output high 2 cycles  
 CMP = PERIOD, output high except for 1 cycle (<100% duty)  
 CMP = PERIOD+1, output high for complete period (100% duty)  
 CMP > PERIOD+1, output high for complete period

The behavior of APWM active-low mode (APWMPOL == 1) is:

CMP = 0x00000000, output high for duration of period (0% duty)  
 CMP = 0x00000001, output low 1 cycle  
 CMP = 0x00000002, output low 2 cycles  
 CMP = PERIOD, output low except for 1 cycle (<100% duty)  
 CMP = PERIOD+1, output low for complete period (100% duty)

CMP > PERIOD+1, output low for complete period

### 15.3.3 Use Cases

The following sections will provide Applications examples and code snippets to show how to configure and operate the eCAP module. For clarity and ease of use, below are useful #defines which will help in the understanding of the examples.

```

// ECCTL1 ( ECAP Control Reg 1)
//=====
// CAPxPOL bits
#define EC_RISING          0x0
#define EC_FALLING        0x1

// CTRRSTx bits
#define EC_ABS_MODE        0x0
#define EC_DELTA_MODE     0x1

// PRESCALE bits
#define EC_BYPASS          0x0
#define EC_DIV1            0x0
#define EC_DIV2            0x1
#define EC_DIV4            0x2
#define EC_DIV6            0x3
#define EC_DIV8            0x4
#define EC_DIV10           0x5

// ECCTL2 ( ECAP Control Reg 2)
//=====
// CONT/ONESHOT bit
#define EC_CONTINUOUS      0x0
#define EC_ONESHOT        0x1

// STOPVALUE bit
#define EC_EVENT1          0x0
#define EC_EVENT2          0x1
#define EC_EVENT3          0x2
#define EC_EVENT4          0x3

// RE-ARM bit
#define EC_ARM             0x1

// TSCTRSTOP bit
#define EC_FREEZE          0x0
#define EC_RUN             0x1

// SYNCO_SEL bit
#define EC_SYNCIN          0x0
#define EC_CTR_PRD         0x1
#define EC_SYNCO_DIS       0x2

// CAP/APWM mode bit
#define EC_CAP_MODE        0x0
#define EC_APWM_MODE       0x1

// APWMPOL bit
#define EC_ACTV_HI         0x0
#define EC_ACTV_LO         0x1

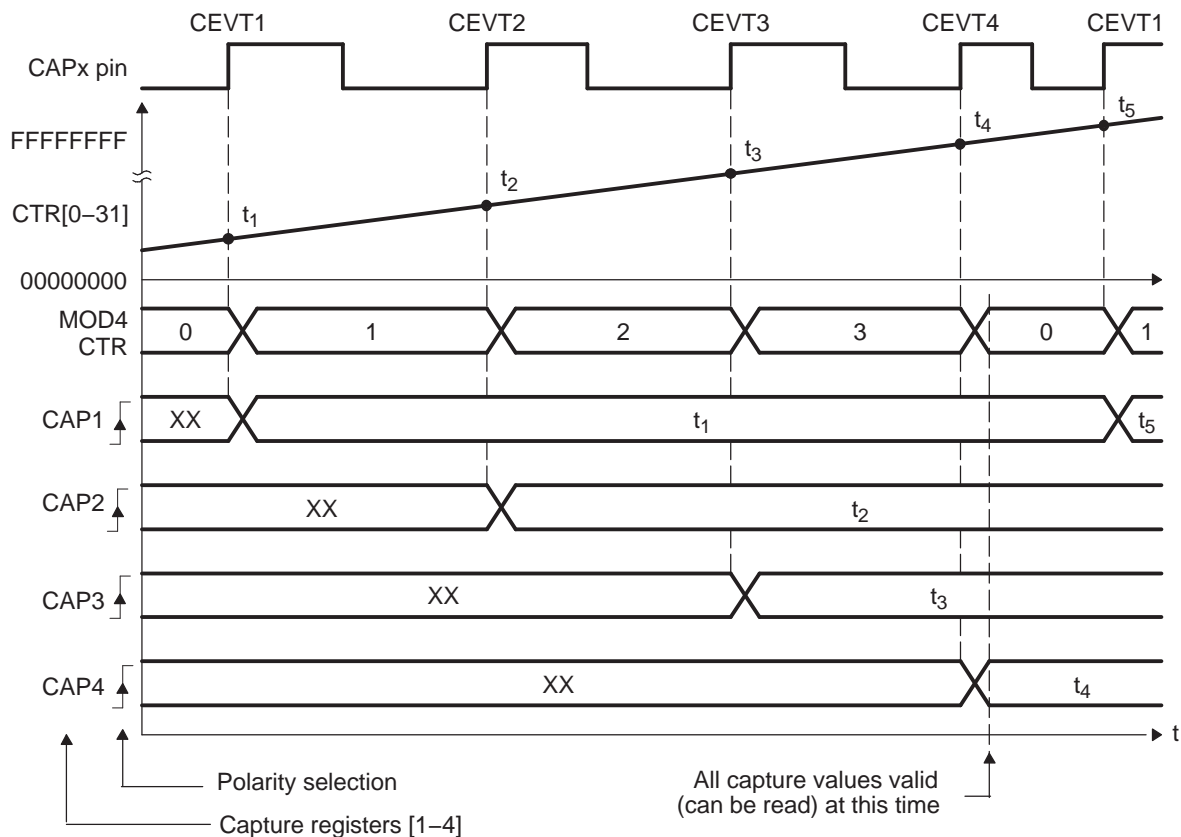

// Generic
#define EC_DISABLE         0x0
#define EC_ENABLE          0x1
#define EC_FORCE           0x1
    
```

### 15.3.3.1 Absolute Time-Stamp Operation Rising Edge Trigger Example

Figure 15-109 shows an example of continuous capture operation (Mod4 counter wraps around). In this figure, TSCTR counts-up without resetting and capture events are qualified on the rising edge only, this gives period (and frequency) information.

On an event, the TSCTR contents (time-stamp) is first captured, then Mod4 counter is incremented to the next state. When the TSCTR reaches FFFF FFFFh (maximum value), it wraps around to 0000 0000h (not shown in Figure 15-109), if this occurs, the CNTOVF (counter overflow) flag is set, and an interrupt (if enabled) occurs, CNTOVF (counter overflow) Flag is set, and an Interrupt (if enabled) occurs. Captured time-stamps are valid at the point indicated by the diagram, after the 4th event, hence event CEVT4 can conveniently be used to trigger an interrupt and the CPU can read data from the CAP<sub>n</sub> registers.

**Figure 15-109. Capture Sequence for Absolute Time-Stamp, Rising Edge Detect**

**Table 15-96. ECAP Initialization for CAP Mode Absolute Time, Rising Edge Trigger**

Register	Bit	Value
ECCTL1	CAP1POL	EC_RISING
ECCTL1	CAP2POL	EC_RISING
ECCTL1	CAP3POL	EC_RISING
ECCTL1	CAP4POL	EC_RISING
ECCTL1	CTRRST1	EC_ABS_MODE
ECCTL1	CTRRST2	EC_ABS_MODE
ECCTL1	CTRRST3	EC_ABS_MODE
ECCTL1	CTRRST4	EC_ABS_MODE
ECCTL1	CAPLDEN	EC_ENABLE
ECCTL1	PRESCALE	EC_DIV1
ECCTL2	CAP_APWM	EC_CAP_MODE
ECCTL2	CONT_ONESHT	EC_CONTINUOUS
ECCTL2	SYNCO_SEL	EC_SYNCO_DIS
ECCTL2	SYNCl_EN	EC_DISABLE
ECCTL2	TSCTRSTOP	EC_RUN

**Example 15-9. Code Snippet for CAP Mode Absolute Time, Rising Edge Trigger**

```

// Code snippet for CAP mode Absolute Time, Rising edge trigger

// Run Time ( e.g. CEVT4 triggered ISR call)
//=====
TSt1 = ECAPxRegs.CAP1;           // Fetch Time-Stamp captured at t1
TSt2 = ECAPxRegs.CAP2;           // Fetch Time-Stamp captured at t2
TSt3 = ECAPxRegs.CAP3;           // Fetch Time-Stamp captured at t3
TSt4 = ECAPxRegs.CAP4;           // Fetch Time-Stamp captured at t4

Period1 = TSt2-TSt1;             // Calculate 1st period
Period2 = TSt3-TSt2;             // Calculate 2nd period
Period3 = TSt4-TSt3;             // Calculate 3rd period
    
```

### 15.3.3.2 Absolute Time-Stamp Operation Rising and Falling Edge Trigger Example

In Figure 15-110 the eCAP operating mode is almost the same as in the previous section except capture events are qualified as either rising or falling edge, this now gives both period and duty cycle information: Period1 =  $t_3 - t_1$ , Period2 =  $t_5 - t_3$ , ...etc. Duty Cycle1 (on-time %) =  $(t_2 - t_1) / \text{Period1} \times 100\%$ , etc. Duty Cycle1 (off-time %) =  $(t_3 - t_2) / \text{Period1} \times 100\%$ , etc.

Figure 15-110. Capture Sequence for Absolute Time-Stamp, Rising and Falling Edge Detect

**Table 15-97. ECAP Initialization for CAP Mode Absolute Time, Rising and Falling Edge Trigger**

Register	Bit	Value
ECCTL1	CAP1POL	EC_RISING
ECCTL1	CAP2POL	EC_FALLING
ECCTL1	CAP3POL	EC_RISING
ECCTL1	CAP4POL	EC_FALLING
ECCTL1	CTRRST1	EC_ABS_MODE
ECCTL1	CTRRST2	EC_ABS_MODE
ECCTL1	CTRRST3	EC_ABS_MODE
ECCTL1	CTRRST4	EC_ABS_MODE
ECCTL1	CAPLDEN	EC_ENABLE
ECCTL1	PRESCALE	EC_DIV1
ECCTL2	CAP_APWM	EC_CAP_MODE
ECCTL2	CONT_ONESHT	EC_CONTINUOUS
ECCTL2	SYNCO_SEL	EC_SYNCO_DIS
ECCTL2	SYNCl_EN	EC_DISABLE
ECCTL2	TSCTRSTOP	EC_RUN

**Example 15-10. Code Snippet for CAP Mode Absolute Time, Rising and Falling Edge Trigger**

```

// Code snippet for CAP mode Absolute Time, Rising & Falling edge triggers

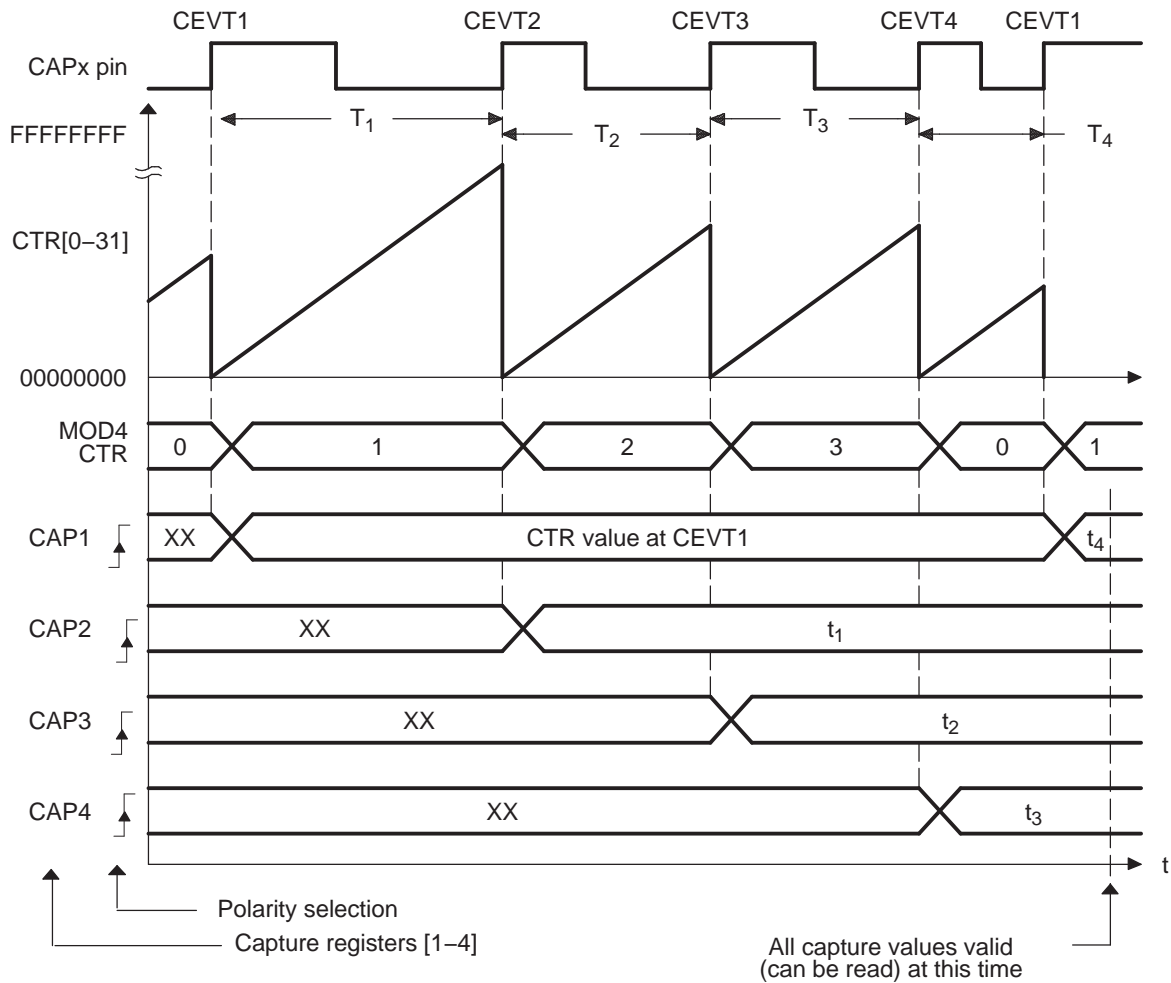

// Run Time ( e.g. CEVT4 triggered ISR call)
//=====
TSt1 = ECAPxRegs.CAP1;           // Fetch Time-Stamp captured at t1
TSt2 = ECAPxRegs.CAP2;           // Fetch Time-Stamp captured at t2
TSt3 = ECAPxRegs.CAP3;           // Fetch Time-Stamp captured at t3
TSt4 = ECAPxRegs.CAP4;           // Fetch Time-Stamp captured at t4

Period1 = TSt3-TSt1;             // Calculate 1st period
DutyOnTime1 = TSt2-TSt1;         // Calculate On time
DutyOffTime1 = TSt3-TSt2;        // Calculate Off time
    
```

15.3.3.3 Time Difference (Delta) Operation Rising Edge Trigger Example

Figure 15-111 shows how the eCAP module can be used to collect Delta timing data from pulse train waveforms. Here Continuous Capture mode (TSCTR counts-up without resetting, and Mod4 counter wraps around) is used. In Delta-time mode, TSCTR is Reset back to Zero on every valid event. Here Capture events are qualified as Rising edge only. On an event, TSCTR contents (time-stamp) is captured first, and then TSCTR is reset to Zero. The Mod4 counter then increments to the next state. If TSCTR reaches FFFF FFFFh (maximum value), before the next event, it wraps around to 0000 0000h and continues, a CANTOVF (counter overflow) Flag is set, and an Interrupt (if enabled) occurs. The advantage of Delta-time Mode is that the CAPn contents directly give timing data without the need for CPU calculations: Period1 = T<sub>1</sub>, Period2 = T<sub>2</sub>,...etc. As shown in Figure 15-111, the CEVT1 event is a good trigger point to read the timing data, T<sub>1</sub>, T<sub>2</sub>, T<sub>3</sub>, T<sub>4</sub> are all valid here.

Figure 15-111. Capture Sequence for Delta Mode Time-Stamp, Rising Edge Detect

**Table 15-98. ECAP Initialization for CAP Mode Delta Time, Rising Edge Trigger**

Register	Bit	Value
ECCTL1	CAP1POL	EC_RISING
ECCTL1	CAP2POL	EC_RISING
ECCTL1	CAP3POL	EC_RISING
ECCTL1	CAP4POL	EC_RISING
ECCTL1	CTRRST1	EC_DELTA_MODE
ECCTL1	CTRRST2	EC_DELTA_MODE
ECCTL1	CTRRST3	EC_DELTA_MODE
ECCTL1	CTRRST4	EC_DELTA_MODE

ECCTL2	SYNCl_EN	EC_DISABLE
ECCTL2	TSCTRSTOP	EC_RUN

**Example 15-11. Code Snippet for CAP Mode Delta Time, Rising Edge Trigger**

```

// Code snippet for CAP mode Delta Time, Rising edge trigger

// Run Time ( e.g. CEVT1 triggered ISR call)
//=====
// Note: here Time-stamp directly represents the Period value.
Period4 = ECAPxRegs.CAP1;    // Fetch Time-Stamp captured at T1
Period1 = ECAPxRegs.CAP2;    // Fetch Time-Stamp captured at T2
Period2 = ECAPxRegs.CAP3;    // Fetch Time-Stamp captured at T3
Period3 = ECAPxRegs.CAP4;    // Fetch Time-Stamp captured at T4
    
```

**15.3.3.4 Time Difference (Delta) Operation Rising and Falling Edge Trigger Example**

In Figure 15-112 the eCAP operating mode is almost the same as in previous section except Capture events are qualified as either Rising or Falling edge, this now gives both Period and Duty cycle information:  $Period1 = T_1 + T_2$ ,  $Period2 = T_3 + T_4$ , ...etc  $Duty Cycle1 (on-time \%) = T_1 / Period1 \times 100\%$ , etc  $Duty Cycle1 (off-time \%) = T_2 / Period1 \times 100\%$ , etc

During initialization, you must write to the active registers for both period and compare. This will then automatically copy the init values into the shadow values. For subsequent compare updates, that is, during run-time, only the shadow registers must be used.

**Figure 15-112. Capture Sequence for Delta Mode Time-Stamp, Rising and Falling Edge Detect**

**Table 15-99. ECAP Initialization for CAP Mode Delta Time, Rising and Falling Edge Triggers**

Register	Bit	Value
ECCTL1	CAP1POL	EC_RISING

ECCTL2	SYNCO_SEL	EC_SYNCO_DIS
ECCTL2	SYNCl_EN	EC_DISABLE
ECCTL2	TSCTRSTOP	EC_RUN

**Example 15-12. Code Snippet for CAP Mode Delta Time, Rising and Falling Edge Triggers**

```

// Code snippet for CAP mode Delta Time, Rising and Falling edge triggers

// Run Time ( e.g. CEVT1 triggered ISR call)
//=====
// Note: here Time-stamp directly represents the Duty cycle values.
DutyOnTime1 = ECAPxRegs.CAP2;    // Fetch Time-Stamp captured at T2
DutyOffTime1 = ECAPxRegs.CAP3;   // Fetch Time-Stamp captured at T3
DutyOnTime2 = ECAPxRegs.CAP4;    // Fetch Time-Stamp captured at T4
DutyOffTime2 = ECAPxRegs.CAP1;   // Fetch Time-Stamp captured at T1

Period1 = DutyOnTime1 + DutyOffTime1;
Period2 = DutyOnTime2 + DutyOffTime2;
    
```

### 15.3.3.5 Application of the APWM Mode

#### 15.3.3.5.1 Simple PWM Generation (Independent Channel/s) Example

In this example, the eCAP module is configured to operate as a PWM generator. Here a very simple single channel PWM waveform is generated from output pin APWM $n$ . The PWM polarity is active high, which means that the compare value (CAP2 reg is now a compare register) represents the on-time (high level) of the period. Alternatively, if the APWMPOL bit is configured for active low, then the compare value represents the off-time.

Figure 15-113. PWM Waveform Details of APWM Mode Operation

**Table 15-100. ECAP Initialization for APWM Mode**

Register	Bit	Value
CAP1	CAP1	0x1000
CTRPHS	CTRPHS	0x0
ECCTL2	CAP_APWM	EC_APWM_MODE
ECCTL2	APWMPOL	EC_ACTV_HI
ECCTL2	SYNCL_EN	EC_DISABLE
ECCTL2	SYNCO_SEL	EC_SYNCO_DIS
ECCTL2	TSTRSTOP	EC_RUN

**Example 15-13. Code Snippet for APWM Mode**

```

// Code snippet for APWM mode Example 1

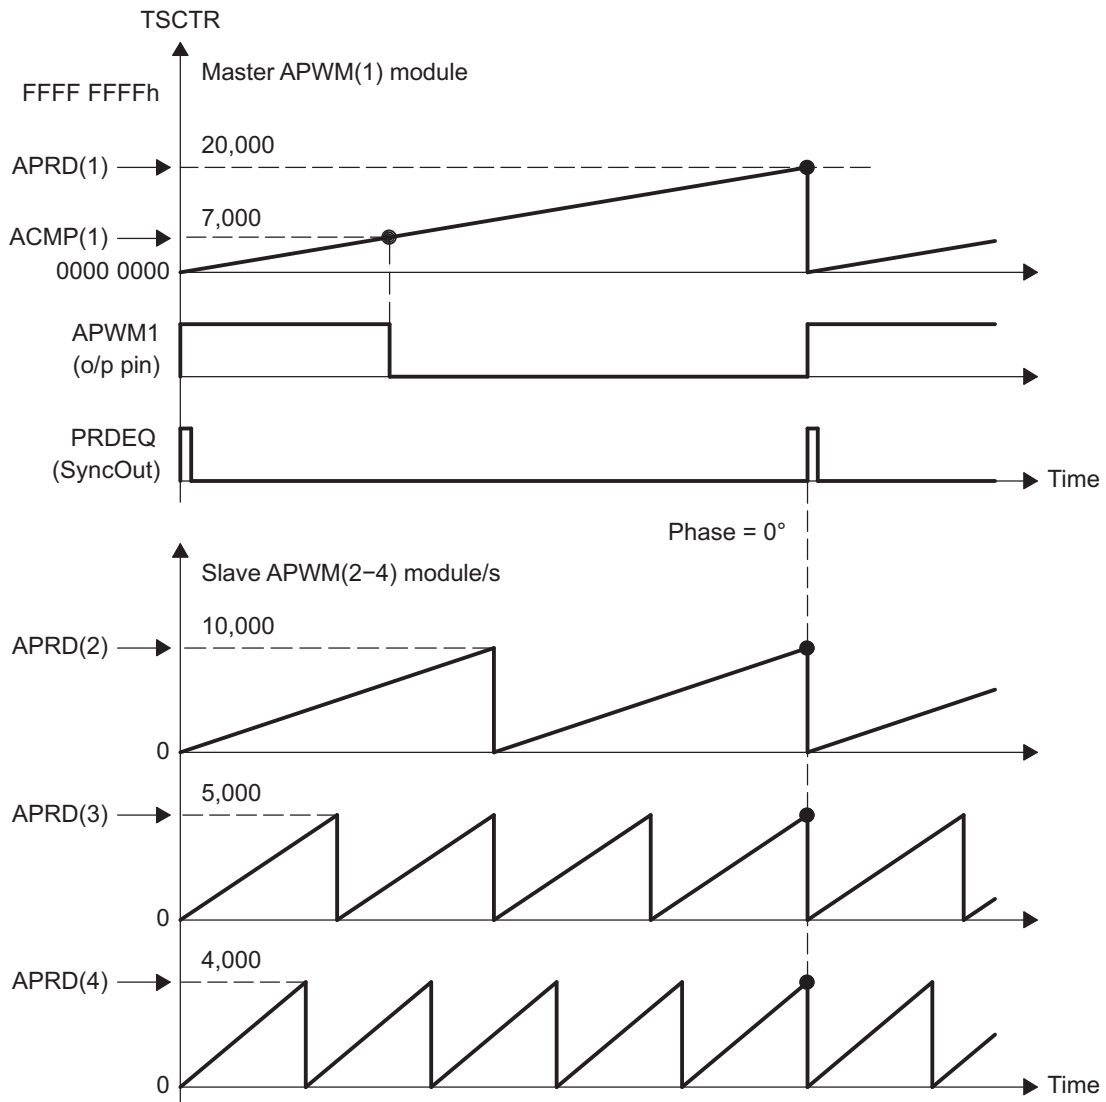

// Run Time (Instant 1, e.g. ISR call)
//=====
    ECAPxRegs.CAP2 = 0x300;      // Set Duty cycle i.e. compare value

// Run Time (Instant 2, e.g. another ISR call)
//=====
    ECAPxRegs.CAP2 = 0x500;      // Set Duty cycle i.e. compare value
    
```

**15.3.3.5.2 Multichannel PWM Generation with Synchronization Example**

Figure 15-114 takes advantage of the synchronization feature between eCAP modules. Here 4 independent PWM channels are required with different frequencies, but at integer multiples of each other to avoid "beat" frequencies. Hence one eCAP module is configured as the Master and the remaining 3 are Slaves all receiving their synch pulse (CTR = PRD) from the master. Note the Master is chosen to have the lower frequency ( $F_1 = 1/20,000$ ) requirement. Here Slave2 Freq =  $2 \times F_1$ , Slave3 Freq =  $4 \times F_1$  and Slave4 Freq =  $5 \times F_1$ . Note here values are in decimal notation. Also, only the APWM1 output waveform is shown.

Figure 15-114. Multichannel PWM Example Using 4 eCAP Modules

**Table 15-101. ECAP1 Initialization for Multichannel PWM Generation with Synchronization**

Register	Bit	Value
CAP1	CAP1	20000
CTRPHS	CTRPHS	0
ECCTL2	CAP_APWM	EC_APWM_MODE

ECCTL2	CAP_APWM	EC_APWM_MODE
ECCTL2	APWMPOL	EC_ACTV_HI
ECCTL2	SYNCl_EN	EC_ENABLE
ECCTL2	SYNCO_SEL	EC_SYNCO_DIS
ECCTL2	TSTRSTOP	EC_RUN

**Example 15-14. Code Snippet for Multichannel PWM Generation with Synchronization**

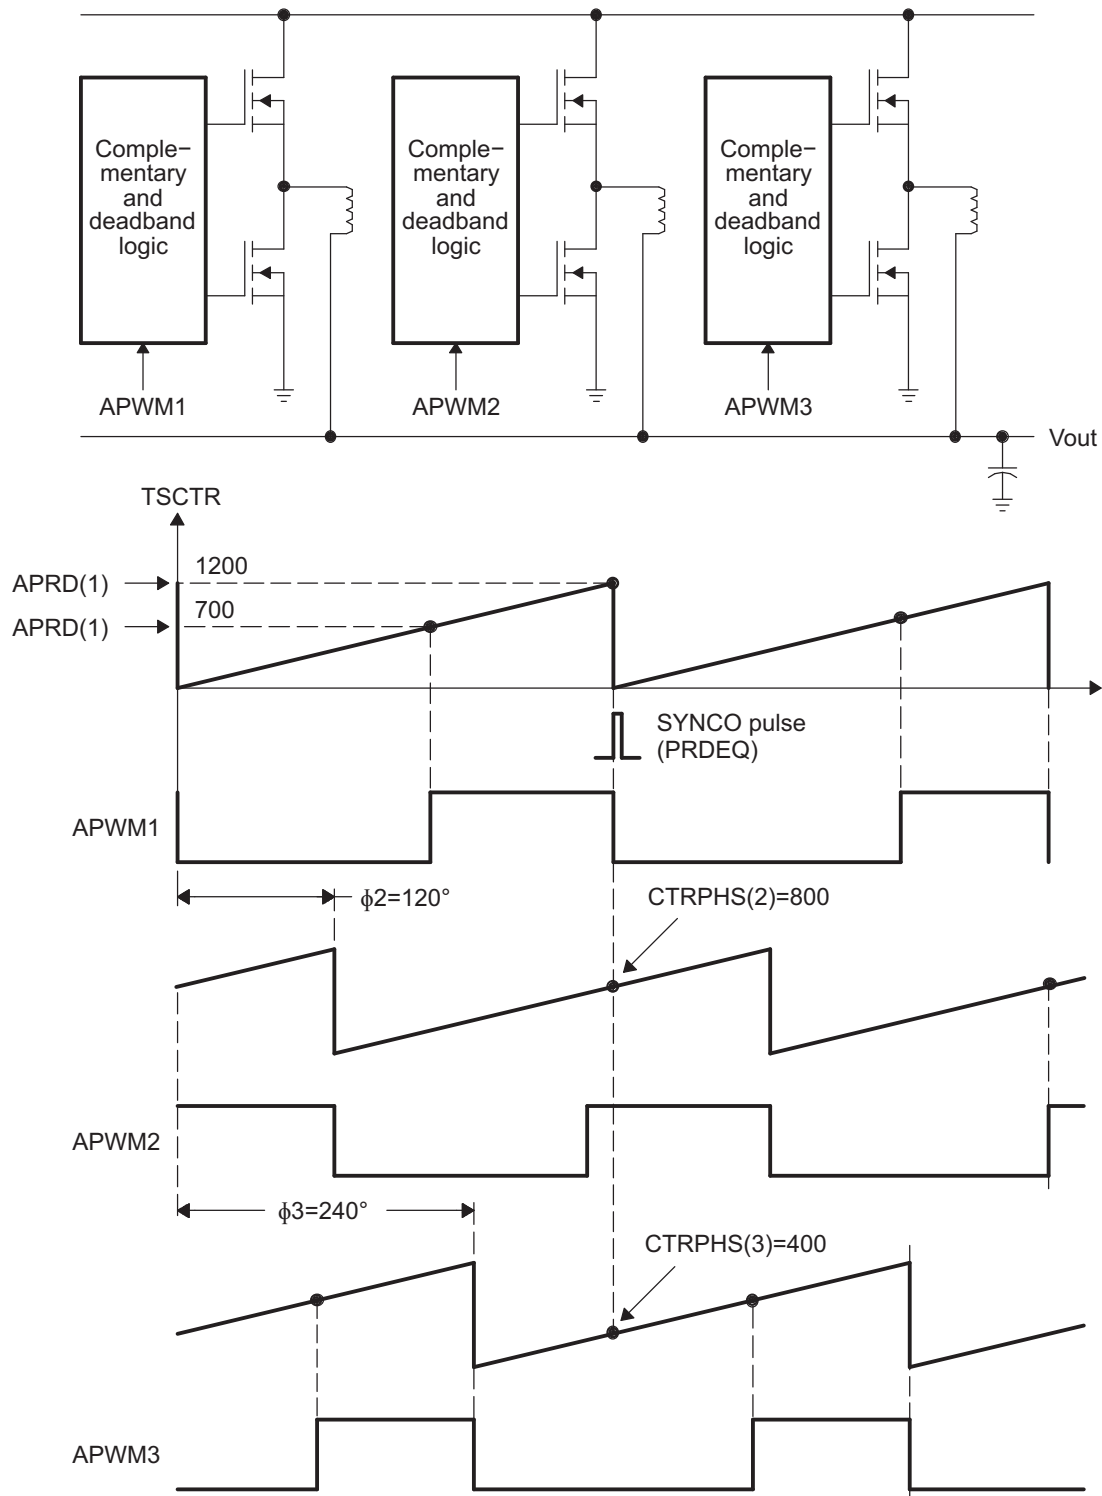

```
// Code snippet for APWM mode Example 2

// Run Time (Note: Example execution of one run-time instant)
//=====
ECAP1Regs.CAP2 = 7000;    // Set Duty cycle i.e., compare value = 7000
ECAP2Regs.CAP2 = 2000;    // Set Duty cycle i.e., compare value = 2000
ECAP3Regs.CAP2 = 550;     // Set Duty cycle i.e., compare value = 550
ECAP4Regs.CAP2 = 6500;    // Set Duty cycle i.e., compare value = 6500
```

**15.3.3.5.3 Multichannel PWM Generation with Phase Control Example**

In [Figure 15-115](#), the Phase control feature of the APWM mode is used to control a 3 phase Interleaved DC/DC converter topology. This topology requires each phase to be off-set by 120° from each other. Hence if “Leg” 1 (controlled by APWM1) is the reference Leg (or phase), that is, 0°, then Leg 2 need 120° off-set and Leg 3 needs 240° off-set. The waveforms in [Figure 15-115](#) show the timing relationship between each of the phases (Legs). Note eCAP1 module is the Master and issues a sync out pulse to the slaves (modules 2, 3) whenever TSCTR = Period value.

Figure 15-115. Multiphase (channel) Interleaved PWM Example Using 3 eCAP Modules

**Table 15-105. ECAP1 Initialization for Multichannel PWM Generation with Phase Control**

Register	Bit	Value
CAP1	CAP1	1200

ECCTL2	SYNCO_SEL	EC_SYNCO_DIS
ECCTL2	TSTRSTOP	EC_RUN

**Example 15-15. Code Snippet for Multichannel PWM Generation with Phase Control**

```
// Code snippet for APWM mode Example 3

// Run Time (Note: Example execution of one run-time instant)
//=====
// All phases are set to the same duty cycle
ECAP1Regs.CAP2 = 700;    // Set Duty cycle i.e. compare value = 700
ECAP2Regs.CAP2 = 700;    // Set Duty cycle i.e. compare value = 700
ECAP3Regs.CAP2 = 700;    // Set Duty cycle i.e. compare value = 700
```

### 15.3.4 Registers

All 32-bit registers are aligned on even address boundaries and are organized in little-endian mode. The 16 least-significant bits of a 32-bit register are located on lowest address (even address).

---

**NOTE:** In APWM mode, writing to CAP1/CAP2 active registers also writes the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 invokes the shadow mode.

---

#### 15.3.4.1 ECAP Registers

Table 15-108 lists the memory-mapped registers for the ECAP. All register offset addresses not listed in Table 15-108 should be considered as reserved locations and the register contents should not be modified.

**Table 15-108. ECAP REGISTERS**

Offset	Acronym	Register Name	Section
0h	TSCTR	Time-Stamp Counter Register	<a href="#">Section 15.3.4.1.1</a>
4h	CTRPHS	Counter Phase Offset Value Register	<a href="#">Section 15.3.4.1.2</a>
8h	CAP1	Capture 1 Register	<a href="#">Section 15.3.4.1.3</a>
Ch	CAP2	Capture 2 Register	<a href="#">Section 15.3.4.1.4</a>
10h	CAP3	Capture 3 Register	<a href="#">Section 15.3.4.1.5</a>

30h	ECCLR	Capture Interrupt Clear Register	<a href="#">Section 15.3.4.1.11</a>
32h	ECFRC	Capture Interrupt Force Register	<a href="#">Section 15.3.4.1.12</a>
5Ch	REVID	Revision ID Register	<a href="#">Section 15.3.4.1.13</a>

### 15.3.4.1.1 TSCTR Register (offset = 0h) [reset = 0h]

TSCTR is shown in [Figure 15-116](#) and described in [Table 15-109](#).

**Figure 15-116. TSCTR Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 15-109. TSCTR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TSCTR	R/W	0h	Active 32 bit counter register that is used as the capture time-base

### 15.3.4.1.2 CTRPHS Register (offset = 4h) [reset = 0h]

CTRPHS is shown in [Figure 15-117](#) and described in [Table 15-110](#).

**Figure 15-117. CTRPHS Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 15-110. CTRPHS Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	CTRPHS	R/W	0h	Counter phase value register that can be programmed for phase lag/lead. This register shadows TSCTR and is loaded into TSCTR upon either a SYNCI event or S/W force via a control bit. Used to achieve phase control synchronization with respect to other eCAP and EPWM time-bases.

### 15.3.4.1.3 CAP1 Register (offset = 8h) [reset = 0h]

CAP1 is shown in [Figure 15-118](#) and described in [Table 15-111](#).

**Figure 15-118. CAP1 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 15-111. CAP1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	CAP1	R/W	0h	This register can be loaded (written) by: (a) Time-Stamp (that is, counter value) during a capture event. (b) Software may be useful for test purposes. (c) APRD active register when used in APWM mode.

#### 15.3.4.1.4 CAP2 Register (offset = Ch) [reset = 0h]

CAP2 is shown in [Figure 15-119](#) and described in [Table 15-112](#).

**Figure 15-119. CAP2 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 15-112. CAP2 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	CAP2	R/W	0h	This register can be loaded (written) by: (a) Time-Stamp (that is, counter value) during a capture event. (b) Software may be useful for test purposes. (c) APRD active register when used in APWM mode.

### 15.3.4.1.5 CAP3 Register (offset = 10h) [reset = 0h]

CAP3 is shown in [Figure 15-120](#) and described in [Table 15-113](#).

**Figure 15-120. CAP3 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 15-113. CAP3 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	CAP3	R/W	0h	In CMP mode, this is a time-stamp capture register. In APWM mode, this is the period shadow (APRD) register. You update the PWM period value through this register. In this mode, CAP3 shadows CAP1.

### 15.3.4.1.6 CAP4 Register (offset = 14h) [reset = 0h]

CAP4 is shown in [Figure 15-121](#) and described in [Table 15-114](#).

**Figure 15-121. CAP4 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 15-114. CAP4 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	CAP4	R/W	0h	In CMP mode, this is a time-stamp capture register. In APWM mode, this is the compare shadow (ACMP) register. You update the PWM compare value through this register. In this mode, CAP4 shadows CAP2.

### 15.3.4.1.7 ECCTL1 Register (offset = 28h) [reset = 0h]

ECCTL1 is shown in [Figure 15-122](#) and described in [Table 15-115](#).

**Figure 15-122. ECCTL1 Register**

15	14	13	12	11	10	9	8

1	CTRRST1	R/W	0h	Counter Reset on Capture Event 1 0x0 = Do not reset counter on Capture Event 1 (absolute time stamp) 0x1 = Reset counter after Event 1 time-stamp has been captured (used in difference mode operation)
0	CAP1POL	R/W	0h	Capture Event 1 Polarity select 0x0 = Capture Event 1 triggered on a rising edge (RE) 0x1 = Capture Event 1 triggered on a falling edge (FE)

### 15.3.4.1.8 ECCTL2 Register (offset = 2Ah) [reset = 0h]

ECCTL2 is shown in [Figure 15-123](#) and described in [Table 15-116](#).

**Figure 15-123. ECCTL2 Register**

15	14	13	12	11	10	9	8
Reserved					APWMPOL	CAP_APWM	SWSYNC
R-0h					R/W-0h	R/W-0h	R/W-0h
7	6	5	4	3	2	1	0
SYNCO_SEL		SYNCL_EN	TSCTRSTOP	RE-ARM	STOP_WRAP		CONT_ONESHT
R/W-0h		R/W-0h	R/W-0h	R/W-0h	R/W-0h		R/W-0h

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 15-116. ECCTL2 Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-11	Reserved	R	0h	
10	APWMPOL	R/W	0h	APWM output polarity select. This is applicable only in APWM operating mode 0x0 = Output is active high (Compare value defines high time) 0x1 = Output is active low (Compare value defines low time)
9	CAP_APWM	R/W	0h	CAP/APWM operating mode select 0x0 = ECAP module operates in capture mode. This mode forces the following configuration: Inhibits TSCTR resets via PRDEQ event. Inhibits shadow loads on CAP1 and 2 registers. Permits user to enable CAP1-4 register load. ECAPn/APWMn pin operates as a capture input. 0x1 = ECAP module operates in APWM mode. This mode forces the following configuration: Resets TSCTR on PRDEQ event (period boundary). Permits shadow loading on CAP1 and 2 registers. Disables loading of time-stamps into CAP1-4 registers. ECAPn/APWMn pin operates as a APWM output.
8	SWSYNC	R/W	0h	Software-forced Counter (TSCTR) Synchronizing. This provides a convenient software method to synchronize some or all ECAP time bases. In APWM mode, the synchronizing can also be done via the PRDEQ event. Note: Selecting PRDEQ is meaningful only in APWM mode. However, you can choose it in CAP mode if you find doing so useful. 0x0 = Writing a zero has no effect. Reading always returns a zero 0x1 = Writing a one forces a TSCTR shadow load of current ECAP module and any ECAP modules down-stream providing the SYNCO_SEL bits are 0,0. After writing a 1, this bit returns to a zero.
7-6	SYNCO_SEL	R/W	0h	Sync-Out Select 0x0 = Select sync-in event to be the sync-out signal (pass through) 0x1 = Select PRDEQ event to be the sync-out signal 0x2 = Disable sync out signal 0x3 = Disable sync out signal
5	SYNCL_EN	R/W	0h	Counter (TSCTR) Sync-In select mode 0x0 = Disable sync-in option 0x1 = Enable counter (TSCTR) to be loaded from CTRPHS register upon either a SYNCL signal or a S/W force event.
4	TSCTRSTOP	R/W	0h	Time Stamp (TSCTR) Counter Stop (freeze) Control 0x0 = TSCTR stopped 0x1 = TSCTR free-running

**Table 15-116. ECCTL2 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3	RE-ARM	R/W	0h	One-Shot Re-Arming Control, that is, wait for stop trigger. Note: The re-arm function is valid in one shot or continuous mode. 0x0 = Has no effect (reading always returns a 0) 0x1 = Arms the one-shot sequence as follows: 1) Resets the Mod4 counter to zero. 2) Unfreezes the Mod4 counter. 3) Enables capture register loads.
2-1	STOP_WRAP	R/W	0h	Stop value for one-shot mode. This is the number (between 1 and 4) of captures allowed to occur before the CAP (1 through 4) registers are frozen, that is, capture sequence is stopped. Wrap value for continuous mode. This is the number (between 1 and 4) of the capture register in which the circular buffer wraps around and starts again. Notes: STOP_WRAP is compared to Mod4 counter and, when equal, two actions occur: (1) Mod4 counter is stopped (frozen). (2) Capture register loads are inhibited. In one-shot mode, further interrupt events are blocked until re-armed. 0x0 = Stop after Capture Event 1 in one-shot mode. Wrap after Capture Event 1 in continuous mode. 0x1 = Stop after Capture Event 2 in one-shot mode. Wrap after Capture Event 2 in continuous mode. 0x2 = Stop after Capture Event 3 in one-shot mode. Wrap after Capture Event 3 in continuous mode. 0x3 = Stop after Capture Event 4 in one-shot mode. Wrap after Capture Event 4 in continuous mode.
0	CONT_ONESHT	R/W	0h	Continuous or one-shot mode control (applicable only in capture mode) 0x0 = Operate in continuous mode 0x1 = Operate in one-shot mode

### 15.3.4.1.9 ECEINT Register (offset = 2Ch) [reset = 0h]

ECEINT is shown in [Figure 15-124](#) and described in [Table 15-117](#).

The interrupt enable bits (CEVTn) block any of the selected events from generating an interrupt. Events will still be latched into the flag bit (ECFLG register) and can be forced or cleared via the ECFRC and ECCLR registers. The proper procedure for configuring peripheral modes and interrupts is: 1. Disable global interrupts. 2. Stop eCAP counter. 3. Disable eCAP interrupts. 4. Configure peripheral registers. 5. Clear spurious eCAP interrupt flags. 6. Enable eCAP interrupts. 7. Start eCAP counter. 8. Enable global interrupts.

**Figure 15-124. ECEINT Register**

## 15.4 Enhanced Quadrature Encoder Pulse (eQEP) Module

### 15.4.1 Introduction

A single track of slots patterns the periphery of an incremental encoder disk, as shown in [Figure 15-129](#). These slots create an alternating pattern of dark and light lines. The disk count is defined as the number of dark/light line pairs that occur per revolution (lines per revolution). As a rule, a second track is added to generate a signal that occurs once per revolution (index signal: QEPI), which can be used to indicate an absolute position. Encoder manufacturers identify the index pulse using different terms such as index, marker, home position, and zero reference.

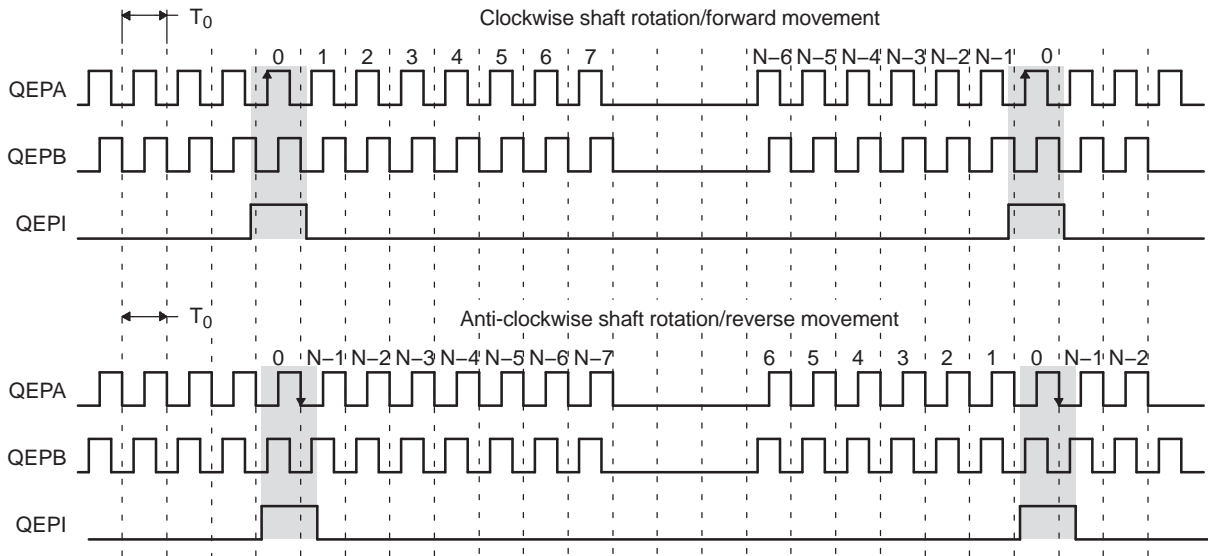

**Figure 15-129. Optical Encoder Disk**

To derive direction information, the lines on the disk are read out by two different photo-elements that "look" at the disk pattern with a mechanical shift of 1/4 the pitch of a line pair between them. This shift is realized with a reticle or mask that restricts the view of the photo-element to the desired part of the disk lines. As the disk rotates, the two photo-elements generate signals that are shifted 90 degrees out of phase from each other. These are commonly called the quadrature QEPA and QEPB signals. The clockwise direction for most encoders is defined as the QEPA channel going positive before the QEPB channel and vice versa as shown in [Figure 15-130](#).

The encoder wheel typically makes one revolution for every revolution of the motor or the wheel may be at a geared rotation ratio with respect to the motor. Therefore, the frequency of the digital signal coming from the QEPA and QEPB outputs varies proportionally with the velocity of the motor. For example, a 2000-line encoder directly coupled to a motor running at 5000 revolutions per minute (rpm) results in a frequency of 166.6 KHz, so by measuring the frequency of either the QEPA or QEPB output, the processor can determine the velocity of the motor.

**Figure 15-130. QEP Encoder Output Signal for Forward/Reverse Movement**

**Legend:** N = lines per revolution

Quadrature encoders from different manufacturers come with two forms of index pulse (gated index pulse or ungated index pulse) as shown in Figure 15-131. A nonstandard form of index pulse is ungated. In the ungated configuration, the index edges are not necessarily coincident with A and B signals. The gated index pulse is aligned to any of the four quadrature edges and width of the index pulse and can be equal to a quarter, half, or full period of the quadrature signal.

**Figure 15-131. Index Pulse Example**

Some typical applications of shaft encoders include robotics and even computer input in the form of a mouse. Inside your mouse you can see where the mouse ball spins a pair of axles (a left/right, and an up/down axle). These axles are connected to optical shaft encoders that effectively tell the computer how fast and in what direction the mouse is moving.

**General Issues:** Estimating velocity from a digital position sensor is a cost-effective strategy in motor control. Two different first order approximations for velocity may be written as:

$$v(k) \approx \frac{x(k) - x(k - 1)}{T} = \frac{\Delta X}{T} \quad (1)$$

$$v(k) \approx \frac{X}{t(k) - t(k - 1)} = \frac{X}{\Delta T} \quad (2)$$

where

$v(k)$ : Velocity at time instant  $k$

$x(k)$ : Position at time instant  $k$

$x(k-1)$ : Position at time instant  $k - 1$

$T$ : Fixed unit time or inverse of velocity calculation rate

$\Delta X$ : Incremental position movement in unit time

$t(k)$ : Time instant " $k$ "

$t(k-1)$ : Time instant " $k - 1$ "

$X$ : Fixed unit position

$\Delta T$ : Incremental time elapsed for unit position movement.

[Equation 1](#) is the conventional approach to velocity estimation and it requires a time base to provide unit time event for velocity calculation. Unit time is basically the inverse of the velocity calculation rate.

The encoder count (position) is read once during each unit time event. The quantity  $[x(k) - x(k-1)]$  is formed by subtracting the previous reading from the current reading. Then the velocity estimate is computed by multiplying by the known constant  $1/T$  (where  $T$  is the constant time between unit time events and is known in advance).

Estimation based on [Equation 1](#) has an inherent accuracy limit directly related to the resolution of the position sensor and the unit time period  $T$ . For example, consider a 500-line per revolution quadrature encoder with a velocity calculation rate of 400 Hz. When used for position the quadrature encoder gives a four-fold increase in resolution, in this case, 2000 counts per revolution. The minimum rotation that can be detected is therefore 0.0005 revolutions, which gives a velocity resolution of 12 rpm when sampled at 400 Hz. While this resolution may be satisfactory at moderate or high speeds, for example, 1% error at 1200 rpm, it would clearly prove inadequate at low speeds. In fact, at speeds below 12 rpm, the speed estimate would erroneously be zero much of the time.

At low speed, [Equation 2](#) provides a more accurate approach. It requires a position sensor that outputs a fixed interval pulse train, such as the aforementioned quadrature encoder. The width of each pulse is defined by motor speed for a given sensor resolution. [Equation 2](#) can be used to calculate motor speed by measuring the elapsed time between successive quadrature pulse edges. However, this method suffers from the opposite limitation, as does [Equation 1](#). A combination of relatively large motor speeds and high sensor resolution makes the time interval  $\Delta T$  small, and thus more greatly influenced by the timer resolution. This can introduce considerable error into high-speed estimates.

For systems with a large speed range (that is, speed estimation is needed at both low and high speeds), one approach is to use [Equation 2](#) at low speed and have the software switch over to [Equation 1](#) when the motor speed rises above some specified threshold.

## 15.4.2 Functional Description

This section provides the eQEP inputs and functional description.

---

**NOTE:** Multiple identical eQEP modules can be contained in a system. The number of modules is device-dependent and is based on target application needs. In this document, the letter x within a signal or module name is used to indicate a generic eQEP instance on a device.

---

### 15.4.2.1 EQEP Inputs

The eQEP inputs include two pins for quadrature-clock mode or direction-count mode, an index (or 0 marker), and a strobe input.

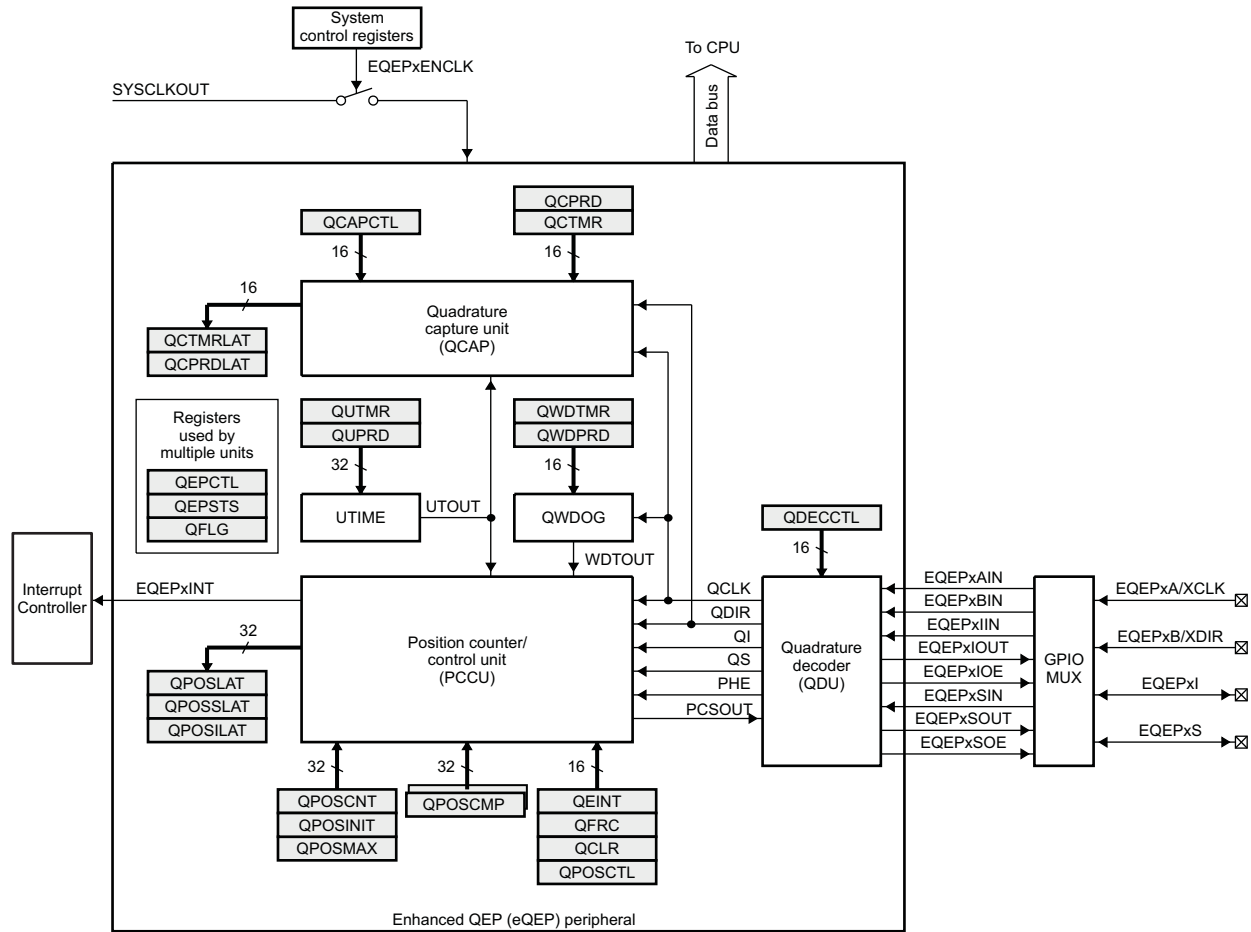

- **QEPA/XCLK and QEPB/XDIR:** These two pins can be used in quadrature-clock mode or direction-count mode.
  - **Quadrature-clock Mode:** The eQEP encoders provide two square wave signals (A and B) 90 electrical degrees out of phase whose phase relationship is used to determine the direction of rotation of the input shaft and number of eQEP pulses from the index position to derive the relative position information. For forward or clockwise rotation, QEPA signal leads QEPB signal and vice versa. The quadrature decoder uses these two inputs to generate quadrature-clock and direction signals.
  - **Direction-count Mode:** In direction-count mode, direction and clock signals are provided directly from the external source. Some position encoders have this type of output instead of quadrature output. The QEPA pin provides the clock input and the QEPB pin provides the direction input.
- **QEPI: Index or Zero Marker:** The eQEP encoder uses an index signal to assign an absolute start position from which position information is incrementally encoded using quadrature pulses. This pin is connected to the index output of the eQEP encoder to optionally reset the position counter for each revolution. This signal can be used to initialize or latch the position counter on the occurrence of a desired event on the index pin.
- **QEPS: Strobe Input:** This general-purpose strobe signal can initialize or latch the position counter on the occurrence of a desired event on the strobe pin. This signal is typically connected to a sensor or limit switch to notify that the motor has reached a defined position.

### 15.4.2.2 Functional Description

The eQEP peripheral contains the following major functional units (as shown in [Figure 15-132](#)):

- Programmable input qualification for each pin (part of the GPIO MUX)
- Quadrature decoder unit (QDU)
- Position counter and control unit for position measurement (PCCU)
- Quadrature edge-capture unit for low-speed measurement (QCAP)
- Unit time base for speed/frequency measurement (UTIME)
- Watchdog timer for detecting stalls (QWDOG)

Figure 15-132. Functional Block Diagram of the eQEP Peripheral

### 15.4.2.3 Quadrature Decoder Unit (QDU)

Figure 15-133 shows a functional block diagram of the QDU.

Figure 15-133. Functional Block Diagram of Decoder Unit

### 15.4.2.3.1 Position Counter Input Modes

Clock and direction input to position counter is selected using the QSRC bit in the eQEP decoder control register (QDECCTL), based on interface input requirement as follows:

- Quadrature-count mode
- Direction-count mode
- UP-count mode
- DOWN-count mode

#### 15.4.2.3.1.1 Quadrature Count Mode

The quadrature decoder generates the direction and clock to the position counter in quadrature count mode.

**Direction Decoding**— The direction decoding logic of the eQEP circuit determines which one of the sequences (QEPA, QEPB) is the leading sequence and accordingly updates the direction information in the QDF bit in the eQEP status register (QEPSTS). [Table 15-122](#) and [Figure 15-134](#) show the direction decoding logic in truth table and state machine form. Both edges of the QEPA and QEPB signals are sensed to generate count pulses for the position counter. Therefore, the frequency of the clock generated by the eQEP logic is four times that of each input sequence. [Figure 15-135](#) shows the direction decoding and clock generation from the eQEP input signals.

**Phase Error Flag**— In normal operating conditions, quadrature inputs QEPA and QEPB will be 90 degrees out of phase. The phase error flag (PHE) is set in the QFLG register when edge transition is detected simultaneously on the QEPA and QEPB signals to optionally generate interrupts. State transitions marked by dashed lines in [Figure 15-134](#) are invalid transitions that generate a phase error.

**Count Multiplication**— The eQEP position counter provides 4x times the resolution of an input clock by generating a quadrature-clock (QCLK) on the rising/falling edges of both eQEP input clocks (QEPA and QEPB) as shown in [Figure 15-135](#).

**Reverse Count**— In normal quadrature count operation, QEPA input is fed to the QA input of the quadrature decoder and the QEPB input is fed to the QB input of the quadrature decoder. Reverse counting is enabled by setting the SWAP bit in the eQEP decoder control register (QDECCTL). This will swap the input to the quadrature decoder thereby reversing the counting direction.

**Table 15-122. Quadrature Decoder Truth Table**

Previous Edge	Present Edge	QDIR	QPOSCNT
QA↑	QB↑	UP	Increment
	QB↓	DOWN	Decrement
	QA↓	TOGGLE	Increment or Decrement
QA↓	QB↓	UP	Increment
	QB↑	DOWN	Decrement
	QA↑	TOGGLE	Increment or Decrement
QB↑	QA↑	DOWN	Increment
	QA↓	UP	Decrement
	QB↓	TOGGLE	Increment or Decrement
QB↓	QA↓	DOWN	Increment
	QA↑	UP	Decrement
	QB↑	TOGGLE	Increment or Decrement

Figure 15-134. Quadrature Decoder State Machine

Figure 15-135. Quadrature-clock and Direction Decoding

### 15.4.2.3.1.2 Direction-count Mode

Some position encoders provide direction and clock outputs, instead of quadrature outputs. In such cases, direction-count mode can be used. QEPA input will provide the clock for position counter and the QEPB input will have the direction information. The position counter is incremented on every rising edge of a QEPA input when the direction input is high and decremented when the direction input is low.

### 15.4.2.3.1.3 Up-Count Mode

The counter direction signal is hard-wired for up count and the position counter is used to measure the frequency of the QEPA input. Setting of the XCR bit in the eQEP decoder control register (QDECCTL) enables clock generation to the position counter on both edges of the QEPA input, thereby increasing the measurement resolution by 2x factor.

### 15.4.2.3.1.4 Down-Count Mode

The counter direction signal is hardwired for a down count and the position counter is used to measure the frequency of the QEPA input. Setting of the XCR bit in the eQEP decoder control register (QDECCTL) enables clock generation to the position counter on both edges of a QEPA input, thereby increasing the measurement resolution by 2x factor.

### 15.4.2.3.2 eQEP Input Polarity Selection

Each eQEP input can be inverted using the in the eQEP decoder control register (QDECCTL[8:5]) control bits. As an example, setting of the QIP bit in QDECCTL inverts the index input.

### 15.4.2.3.3 Position-Compare Sync Output

The eQEP peripheral includes a position-compare unit that is used to generate the position-compare sync signal on compare match between the position counter register (QPOSCNT) and the position-compare register (QPOSCMP). This sync signal can be output using an index pin or strobe pin of the EQEP peripheral.

Setting the SOEN bit in the eQEP decoder control register (QDECCTL) enables the position-compare sync output and the SPSEL bit in QDECCTL selects either an eQEP index pin or an eQEP strobe pin.

### 15.4.2.4 Position Counter and Control Unit (PCCU)

The position counter and control unit provides two configuration registers (QEPCTL and QPOSCTL) for setting up position counter operational modes, position counter initialization/latch modes and position-compare logic for sync signal generation.

#### 15.4.2.4.1 Position Counter Operating Modes

Position counter data may be captured in different manners. In some systems, the position counter is accumulated continuously for multiple revolutions and the position counter value provides the position information with respect to the known reference. An example of this is the quadrature encoder mounted on the motor controlling the print head in the printer. Here the position counter is reset by moving the print head to the home position and then position counter provides absolute position information with respect to home position.

In other systems, the position counter is reset on every revolution using index pulse and position counter provides rotor angle with respect to index pulse position.

Position counter can be configured to operate in following four modes

- Position Counter Reset on Index Event
- Position Counter Reset on Maximum Position
- Position Counter Reset on the first Index Event
- Position Counter Reset on Unit Time Out Event (Frequency Measurement)

In all the above operating modes, position counter is reset to 0 on overflow and to QPOS MAX register value on underflow. Overflow occurs when the position counter counts up after QPOS MAX value. Underflow occurs when position counter counts down after "0". Interrupt flag is set to indicate overflow/underflow in QFLG register.

**15.4.2.4.1.1 Position Counter Reset on Index Event (QEPCTL[PCRM] = 00)**

If the index event occurs during the forward movement, then position counter is reset to 0 on the next eQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the QPOS MAX register on the next eQEP clock.

First index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in QEPSTS registers, it also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for index event reset operation.

For example, if the first reset operation occurs on the falling edge of QEPB during the forward direction, then all the subsequent reset must be aligned with the falling edge of QEPB for the forward rotation and on the rising edge of QEPB for the reverse rotation as shown in Figure 15-136.

The position-counter value is latched to the QPOSILAT register and direction information is recorded in the QEPSTS[QDLF] bit on every index event marker. The position-counter error flag (QEPSTS[PCEF]) and error interrupt flag (QFLG[PCE]) are set if the latched value is not equal to 0 or QPOS MAX. The position-counter error flag (QEPSTS[PCEF]) is updated on every index event marker and an interrupt flag (QFLG[PCE]) will be set on error that can be cleared only through software.

The index event latch configuration QEPCTL[IEL] bits are ignored in this mode and position counter error flag/interrupt flag are generated only in index event reset mode.

**Figure 15-136. Position Counter Reset by Index Pulse for 1000 Line Encoder (QPOS MAX = 3999 or F9Fh)**

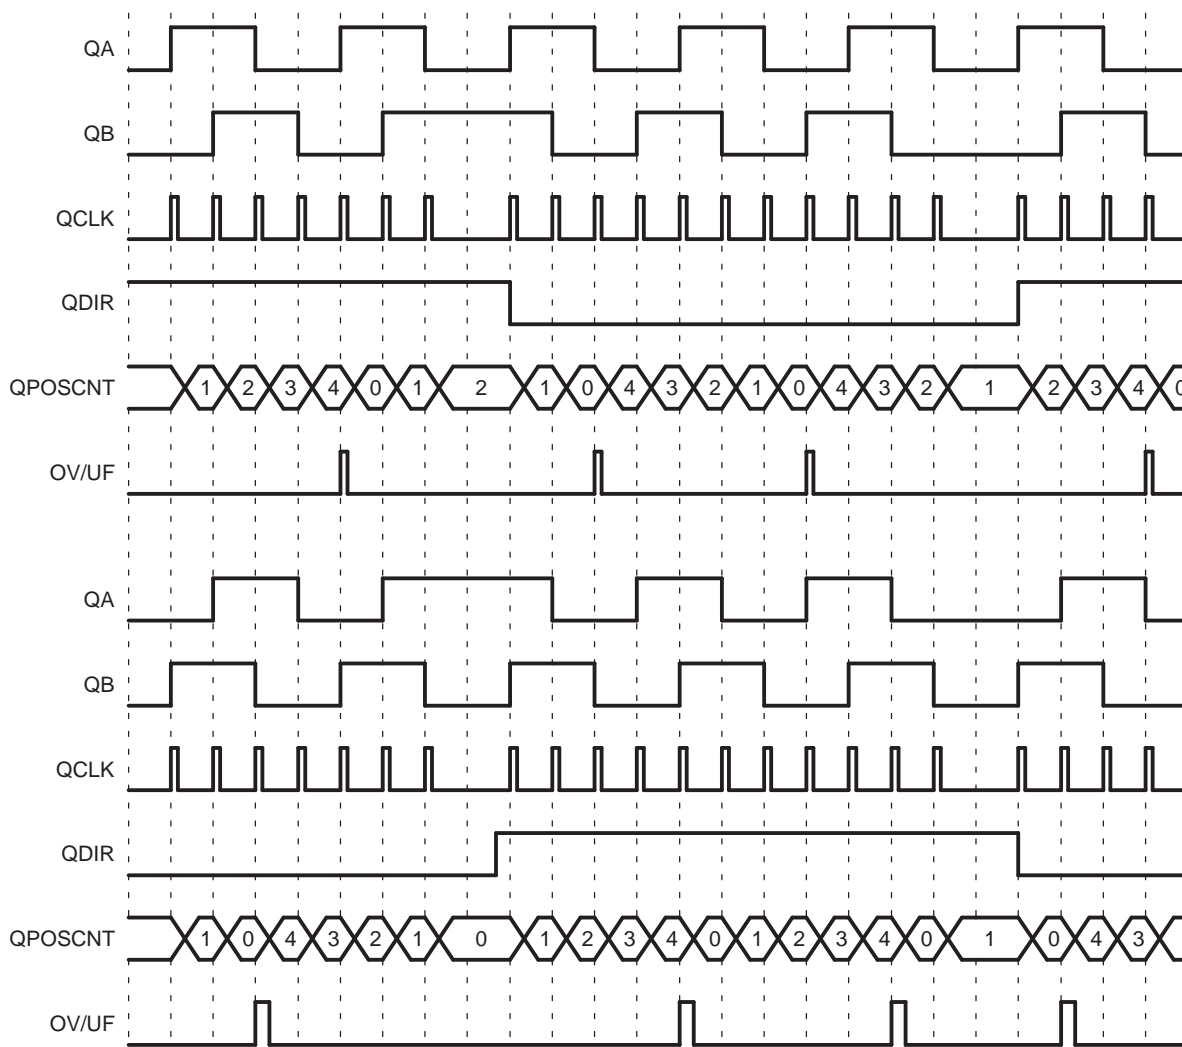

**15.4.2.4.1.2 Position Counter Reset on Maximum Position (QEPCTL[PCRM]=01)**

If the position counter is equal to QPOSMAX, then the position counter is reset to 0 on the next eQEP clock for forward movement and position counter overflow flag is set. If the position counter is equal to ZERO, then the position counter is reset to QPOSMAX on the next QEP clock for reverse movement and position counter underflow flag is set. Figure 15-137 shows the position counter reset operation in this mode.

First index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in the QEPSTS registers; it also remembers the quadrature edge on the first index marker so that the same relative quadrature transition is used for the software index marker (QEPCTL[IEL]=11).

**Figure 15-137. Position Counter Underflow/Overflow (QPOSMAX = 4)**

#### **15.4.2.4.1.3 Position Counter Reset on the First Index Event (QEPCTL[PCRM] = 10)**

If the index event occurs during forward movement, then the position counter is reset to 0 on the next eQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the QPOSMAX register on the next eQEP clock. Note that this is done only on the first occurrence and subsequently the position counter value is not reset on an index event; rather, it is reset based on maximum position as described in [Section 15.4.2.4.1.2](#).

First index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in QEPSTS registers. It also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for software index marker (QEPCTL[IEL]=11).

#### **15.4.2.4.1.4 Position Counter Reset on Unit Time out Event (QEPCTL[PCRM] = 11)**

In this mode, the QPOSCNT value is latched to the QPOSLAT register and then the QPOSCNT is reset (to 0 or QPOSMAX, depending on the direction mode selected by QDECCTL[QSRC] bits on a unit time event). This is useful for frequency measurement.

#### **15.4.2.4.2 Position Counter Latch**

The eQEP index and strobe input can be configured to latch the position counter (QPOSCNT) into QPOSILAT and QPOSSLAT, respectively, on occurrence of a definite event on these pins.

##### **15.4.2.4.2.1 Index Event Latch**

In some applications, it may not be desirable to reset the position counter on every index event and instead it may be required to operate the position counter in full 32-bit mode (QEPCTL[PCRM] = 01 and QEPCTL[PCRM] = 10 modes).

In such cases, the eQEP position counter can be configured to latch on the following events and direction information is recorded in the QEPSTS[QDLF] bit on every index event marker.

- Latch on Rising edge (QEPCTL[IEL] = 01)
- Latch on Falling edge (QEPCTL[IEL] = 10)
- Latch on Index Event Marker (QEPCTL[IEL] = 11)

This is particularly useful as an error checking mechanism to check if the position counter accumulated the correct number of counts between index events. As an example, the 1000-line encoder must count 4000 times when moving in the same direction between the index events.

The index event latch interrupt flag (QFLG[IEL]) is set when the position counter is latched to the QPOSILAT register. The index event latch configuration bits (QEPCTZ[IEL]) are ignored when QEPCTL[PCRM] = 00.

**Latch on Rising Edge (QEPCTL[IEL] = 01)**— The position counter value (QPOSCNT) is latched to the QPOSILAT register on every rising edge of an index input.

**Latch on Falling Edge (QEPCTL[IEL] = 10)**— The position counter value (QPOSCNT) is latched to the QPOSILAT register on every falling edge of index input.

**Latch on Index Event Marker/Software Index Marker (QEPCTL[IEL] = 11)**— The first index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in the QEPSTS registers. It also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for latching the position counter (QEPCTL[IEL] = 11).

[Figure 15-138](#) shows the position counter latch using an index event marker.

Figure 15-138. Software Index Marker for 1000-line Encoder (QEPCTL[IEL] = 1)

### 15.4.2.4.2.2 Strobe Event Latch

The position-counter value is latched to the QPOSSLAT register on the rising edge of the strobe input by clearing the QEPCTL[SEL] bit.

If the QEPCTL[SEL] bit is set, then the position counter value is latched to the QPOSSLAT register on the rising edge of the strobe input for forward direction and on the falling edge of the strobe input for reverse direction as shown in Figure 15-139.

The strobe event latch interrupt flag (QFLG[SEL]) is set when the position counter is latched to the QPOSSLAT register.

Figure 15-139. Strobe Event Latch (QEPCTL[SEL] = 1)

#### 15.4.2.4.3 Position Counter Initialization

The position counter can be initialized using following events:

- Index event
- Strobe event
- Software initialization

**Index Event Initialization (IEI)**— The QEPI index input can be used to trigger the initialization of the position counter at the rising or falling edge of the index input.

If the QEPCTL[IEI] bits are 10, then the position counter (QPOSCNT) is initialized with a value in the QPOSINIT register on the rising edge of strobe input for forward direction and on the falling edge of strobe input for reverse direction.

The index event initialization interrupt flag (QFLG[IEI]) is set when the position counter is initialized with a value in the QPOSINIT register.

**Strobe Event Initialization (SEI)**— If the QEPCTL[SEI] bits are 10, then the position counter is initialized with a value in the QPOSINIT register on the rising edge of strobe input.

If the QEPCTL[SEL] bits are 11, then the position counter (QPOSCNT) is initialized with a value in the QPOSINIT register on the rising edge of strobe input for forward direction and on the falling edge of strobe input for reverse direction.

The strobe event initialization interrupt flag (QFLG[SEI]) is set when the position counter is initialized with a value in the QPOSINIT register.

**Software Initialization (SWI)**— The position counter can be initialized in software by writing a 1 to the QEPCTL[SWI] bit, which will automatically be cleared after initialization.

#### 15.4.2.4.4 eQEP Position-compare Unit

The eQEP peripheral includes a position-compare unit that is used to generate a sync output and/or interrupt on a position-compare match. Figure 15-140 shows a diagram. The position-compare (QPOSCMP) register is shadowed and shadow mode can be enabled or disabled using the QPOSCTL[PSSHDW] bit. If the shadow mode is not enabled, the CPU writes directly to the active position compare register.

Figure 15-140. eQEP Position-compare Unit

In shadow mode, you can configure the position-compare unit (QPOSCTL[PCLOAD]) to load the shadow register value into the active register on the following events and to generate the position-compare ready (QFLG[PCR]) interrupt after loading.

- Load on compare match
- Load on position-counter zero event

The position-compare match (QFLG[PCM]) is set when the position-counter value (QPOSCNT) matches with the active position-compare register (QPOSCMP) and the position-compare sync output of the programmable pulse width is generated on compare match to trigger an external device.

For example, if QPOSCMP = 2, the position-compare unit generates a position-compare event on 1 to 2 transitions of the eQEP position counter for forward counting direction and on 3 to 2 transitions of the eQEP position counter for reverse counting direction (see Figure 15-141).

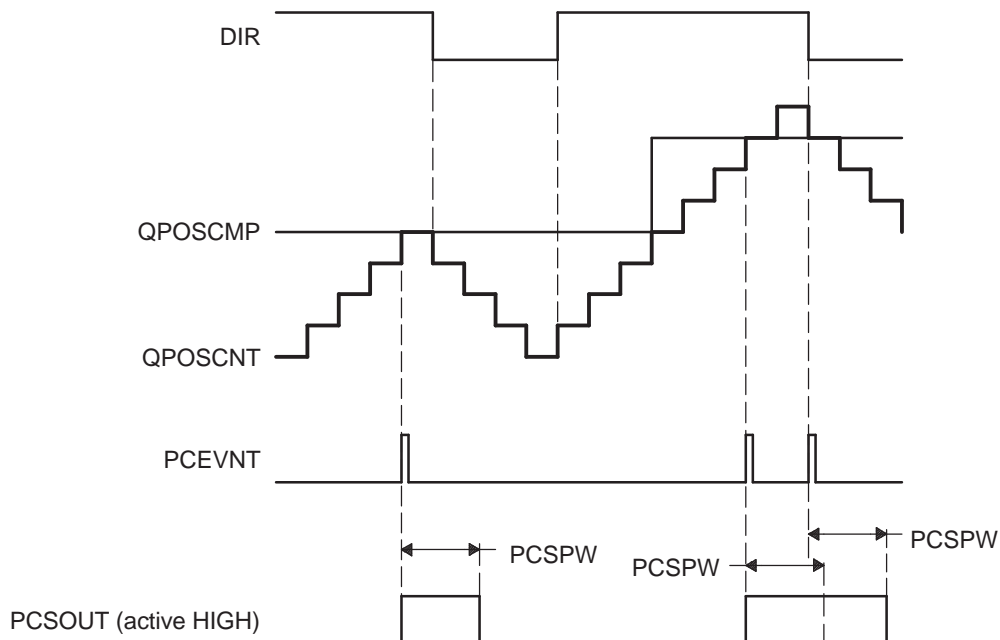

Figure 15-163 shows the layout of the eQEP Position-Compare Control Register (QPOSCTL) and Table 15-138 describes the QPOSCTL bit fields.

**Figure 15-141. eQEP Position-compare Event Generation Points**

The pulse stretcher logic in the position-compare unit generates a programmable position-compare sync pulse output on the position-compare match. In the event of a new position-compare match while a previous position-compare pulse is still active, then the pulse stretcher generates a pulse of specified duration from the new position-compare event as shown in Figure 15-142.

**Figure 15-142. eQEP Position-compare Sync Output Pulse Stretcher**

### 15.4.2.5 eQEP Edge Capture Unit

The eQEP peripheral includes an integrated edge capture unit to measure the elapsed time between the unit position events as shown in [Figure 15-143](#). This feature is typically used for low speed measurement using the following equation:

$$v(k) = \frac{X}{t(k) - t(k - 1)} = \frac{X}{\Delta T} \quad (3)$$

where,

- X - Unit position is defined by integer multiple of quadrature edges (see [Figure 15-144](#))
- $\Delta T$  - Elapsed time between unit position events
- v(k) - Velocity at time instant "k"

The eQEP capture timer (QCTMR) runs from prescaled SYSCLKOUT and the prescaler is programmed by the QCAPCTL[CCPS] bits. The capture timer (QCTMR) value is latched into the capture period register (QCPRD) on every unit position event and then the capture timer is reset, a flag is set in QEPSTS[UPEVNT] to indicate that new value is latched into the QCPRD register. Software can check this status flag before reading the period register for low speed measurement and clear the flag by writing 1.

Time measurement ( $\Delta T$ ) between unit position events will be correct if the following conditions are met:

- No more than 65,535 counts have occurred between unit position events.
- No direction change between unit position events.

The capture unit sets the eQEP overflow error flag (QEPSTS[COEF]) in the event of capture timer overflow between unit position events. If a direction change occurs between the unit position events, then an error flag is set in the status register (QEPSTS[CDEF]).

Capture Timer (QCTMR) and Capture period register (QCPRD) can be configured to latch on following events.

- CPU read of QPOSCNT register
- Unit time-out event

If the QEPCTL[QCLM] bit is cleared, then the capture timer and capture period values are latched into the QCTMRLAT and QCPRDLAT registers, respectively, when the CPU reads the position counter (QPOSCNT).

If the QEPCTL[QCLM] bit is set, then the position counter, capture timer, and capture period values are latched into the QPOSLAT, QCTMRLAT and QCPRDLAT registers, respectively, on unit time out.

[Figure 15-145](#) shows the capture unit operation along with the position counter.

---

**NOTE:** The QCAPCTL register should not be modified dynamically (such as switching CAPCLK prescaling mode from QCLK/4 to QCLK/8). The capture unit must be disabled before changing the prescaler.

---

Figure 15-143. eQEP Edge Capture Unit

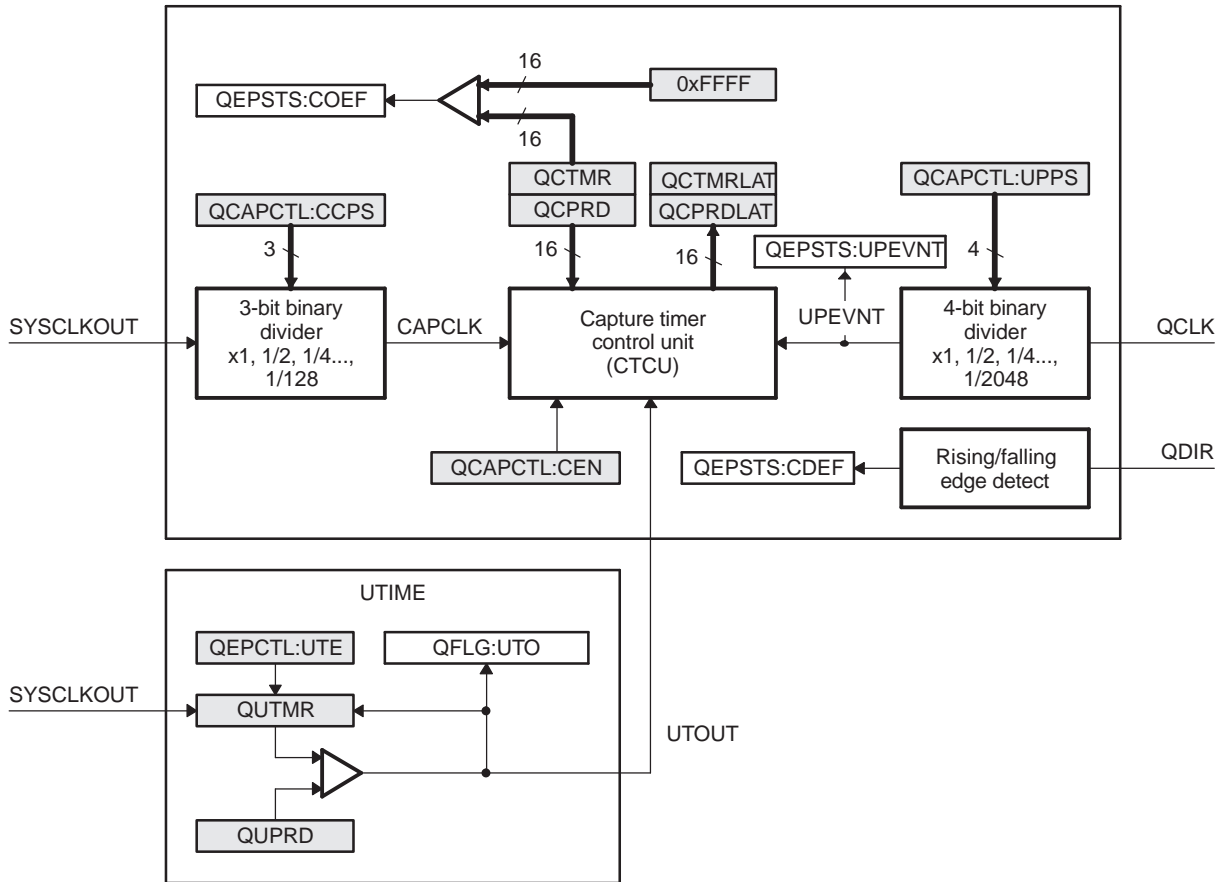

Figure 15-144. Unit Position Event for Low Speed Measurement (QCAPCTL[UPPS] = 0010)

N - Number of quadrature periods selected using QCAPCTL[UPPS] bits

**Figure 15-145. eQEP Edge Capture Unit - Timing Details**

Velocity Calculation Equations:

$$v(k) = \frac{x(k) - x(k-1)}{T} = \frac{\Delta X}{T} \quad (4)$$

where

$v(k)$ : Velocity at time instant  $k$

$x(k)$ : Position at time instant  $k$

$x(k-1)$ : Position at time instant  $k - 1$

$T$ : Fixed unit time or inverse of velocity calculation rate

$\Delta X$ : Incremental position movement in unit time

$X$ : Fixed unit position

$\Delta T$ : Incremental time elapsed for unit position movement

$t(k)$ : Time instant " $k$ "

$t(k-1)$ : Time instant " $k - 1$ "

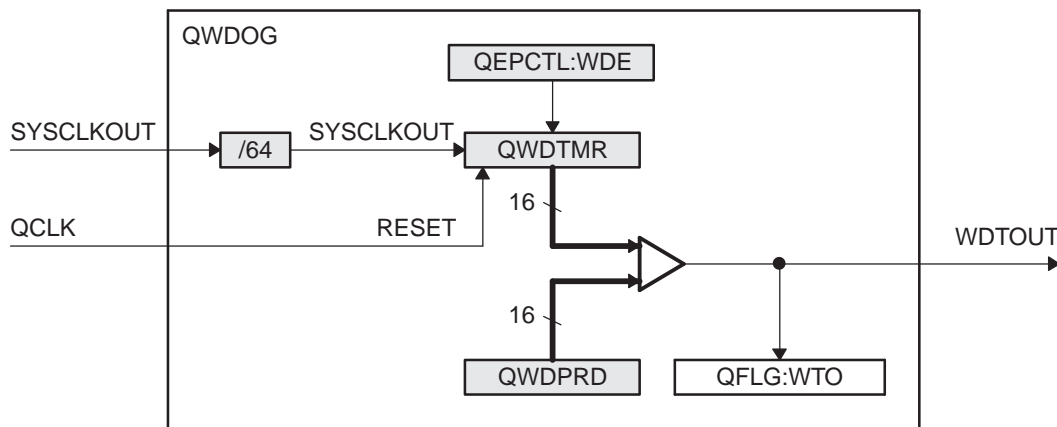

Unit time ( $T$ ) and unit period ( $X$ ) are configured using the QUPRD and QCAPCTL[Upps] registers. Incremental position output and incremental time output is available in the QPOSLAT and QCPRDLAT registers.

Parameter	Relevant Register to Configure or Read the Information
T	Unit Period Register (QUPRD)
$\Delta X$	Incremental Position = QPOSLAT(k) - QPOSLAT(K - 1)
X	Fixed unit position defined by sensor resolution and ZCAPCTL[UPPS] bits
$\Delta T$	Capture Period Latch (QCPRDLAT)

### 15.4.2.6 eQEP Watchdog

The eQEP peripheral contains a 16-bit watchdog timer that monitors the quadrature-clock to indicate proper operation of the motion-control system. The eQEP watchdog timer is clocked from SYSCLKOUT/64 and the quadrature clock event (pulse) resets the watchdog timer. If no quadrature-clock event is detected until a period match ( $QWDPRD = QWDTMR$ ), then the watchdog timer will time out and the watchdog interrupt flag will be set (QFLG[WTO]). The time-out value is programmable through the watchdog period register (QWDPRD).

**Figure 15-146. eQEP Watchdog Timer**

### 15.4.2.7 Unit Timer Base

The eQEP peripheral includes a 32-bit timer (QUTMR) that is clocked by SYSCLKOUT to generate periodic interrupts for velocity calculations. The unit time out interrupt is set (QFLG[UTO]) when the unit timer (QUTMR) matches the unit period register (QUPRD).

The eQEP peripheral can be configured to latch the position counter, capture timer, and capture period values on a unit time out event so that latched values are used for velocity calculation as described in Section [Section 15.4.2.5](#).

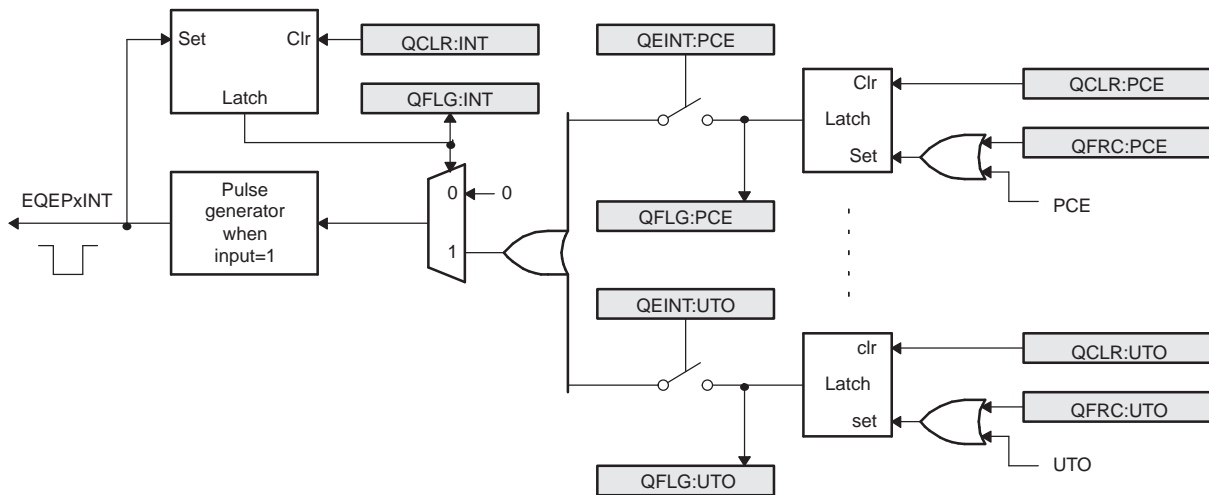

Figure 15-147. eQEP Unit Time Base

### 15.4.2.8 eQEP Interrupt Structure

Figure 15-148 shows how the interrupt mechanism works in the EQEP module.

Figure 15-148. EQEP Interrupt Generation

Eleven interrupt events (PCE, PHE, QDC, WTO, PCU, PCO, PCR, PCM, SEL, IEL, and UTO) can be generated. The interrupt control register (QEINT) is used to enable/disable individual interrupt event sources. The interrupt flag register (QFLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT). An interrupt pulse is generated only to the interrupt controller if any of the interrupt events is enabled, the flag bit is 1 and the INT flag bit is 0. The interrupt service routine will need to clear the global interrupt flag bit and the serviced event, via the interrupt clear register (QCLR), before any other interrupt pulses are generated. You can force an interrupt event by way of the interrupt force register (QFRC), which is useful for test purposes.

Note that the interrupts coming from the eQEP module are also used as DMA events. The interrupt registers should be used to enable and clear the current DMA event in order for the eQEP module to generate subsequent DMA events.

### 15.4.3 eQEP Registers

Table 15-123 lists the registers with their memory locations, sizes, and reset values.

**Table 15-123. eQEP Registers**

### 15.4.3.1 eQEP Position Counter Register (QPOSCNT)

**Figure 15-149. eQEP Position Counter Register (QPOSCNT)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-124. eQEP Position Counter Register (QPOSCNT) Field Descriptions**

Bits	Name	Value	Description
31-0	QPOSCNT	0-FFFF FFFFh	This 32-bit position counter register counts up/down on every eQEP pulse based on direction input. This counter acts as a position integrator whose count value is proportional to position from a give reference point.

### 15.4.3.2 eQEP Position Counter Initialization Register (QPOSINIT)

**Figure 15-150. eQEP Position Counter Initialization Register (QPOSINIT)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-125. eQEP Position Counter Initialization Register (QPOSINIT) Field Descriptions**

Bits	Name	Value	Description
31-0	QPOSINIT	0-FFFF FFFFh	This register contains the position value that is used to initialize the position counter based on external strobe or index event. The position counter can be initialized through software.

### 15.4.3.3 eQEP Maximum Position Count Register (QPOSMAX)

**Figure 15-151. eQEP Maximum Position Count Register (QPOSMAX)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-126. eQEP Maximum Position Count Register (QPOSMAX) Field Descriptions**

Bits	Name	Value	Description
31-0	QPOSMAX	0-FFFF FFFFh	This register contains the maximum position counter value.

### 15.4.3.4 eQEP Position-Compare Register (QPOSCMP)

**Figure 15-152. eQEP Position-Compare Register (QPOSCMP)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-127. eQEP Position-Compare Register (QPOSCMP) Field Descriptions**

Bits	Name	Value	Description
31-0	QPOSCMP	0-FFFF FFFFh	The position-compare value in this register is compared with the position counter (QPOSCNT) to generate sync output and/or interrupt on compare match.

### 15.4.3.5 eQEP Index Position Latch Register (QPOSILAT)

**Figure 15-153. eQEP Index Position Latch Register (QPOSILAT)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-128. eQEP Index Position Latch Register (QPOSILAT) Field Descriptions**

Bits	Name	Value	Description
31-0	QPOSILAT	0-FFFF FFFFh	The position-counter value is latched into this register on an index event as defined by the QEPCTL[IEL] bits.

### 15.4.3.6 eQEP Strobe Position Latch Register (QPOSSLAT)

**Figure 15-154. eQEP Strobe Position Latch Register (QPOSSLAT)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-129. eQEP Strobe Position Latch Register (QPOSSLAT) Field Descriptions**

Bits	Name	Value	Description
31-0	QPOSSLAT	0-FFFF FFFFh	The position-counter value is latched into this register on strobe event as defined by the QEPCTL[SEL] bits.

### 15.4.3.7 eQEP Position Counter Latch Register (QPOSLAT)

**Figure 15-155. eQEP Position Counter Latch Register (QPOSLAT)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-130. eQEP Position Counter Latch Register (QPOSLAT) Field Descriptions**

Bits	Name	Value	Description
31-0	QPOSLAT	0-FFFF FFFFh	The position-counter value is latched into this register on unit time out event.

### 15.4.3.8 eQEP Unit Timer Register (QUTMR)

**Figure 15-156. eQEP Unit Timer Register (QUTMR)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-131. eQEP Unit Timer Register (QUTMR) Field Descriptions**

Bits	Name	Value	Description
31-0	QUTMR	0-FFFF FFFFh	This register acts as time base for unit time event generation. When this timer value matches with unit time period value, unit time event is generated.

### 15.4.3.9 eQEP Unit Period Register (QUPRD)

**Figure 15-157. eQEP Unit Period Register (QUPRD)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-132. eQEP Unit Period Register (QUPRD) Field Descriptions**

Bits	Name	Value	Description
31-0	QUPRD	0-FFFF FFFFh	This register contains the period count for unit timer to generate periodic unit time events to latch the eQEP position information at periodic interval and optionally to generate interrupt.

**15.4.3.10 eQEP Watchdog Timer Register (QWDTMR)**
**Figure 15-158. eQEP Watchdog Timer Register (QWDTMR)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-133. eQEP Watchdog Timer Register (QWDTMR) Field Descriptions**

Bits	Name	Value	Description
15-0	QWDTMR	0-FFFF FFFFh	This register acts as time base for watch dog to detect motor stalls. When this timer value matches with watch dog period value, watch dog timeout interrupt is generated. This register is reset upon edge transition in quadrature-clock indicating the motion.

**15.4.3.11 eQEP Watchdog Period Register (QWDPRD)**
**Figure 15-159. eQEP Watchdog Period Register (QWDPRD)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-134. eQEP Watchdog Period Register (QWDPRD) Field Description**

Bits	Name	Value	Description
15-0	QWDPRD	0-FFFFh	This register contains the time-out count for the eQEP peripheral watch dog timer. When the watchdog timer value matches the watchdog period value, a watchdog timeout interrupt is generated.

**15.4.3.12 QEP Decoder Control Register (QDECCTL)**
**Figure 15-160. QEP Decoder Control Register (QDECCTL)**

## Universal Serial Bus (USB)

---

---

This chapter describes the USB of the device.

Topic	Page
16.1 Introduction .....	1691
16.2 Integration .....	1694
16.3 Functional Description .....	1697
16.4 Supported Use Cases .....	1759
16.5 USB Registers .....	1760

## 16.1 Introduction

The USB controller provides a low-cost connectivity solution for numerous consumer portable devices by providing a mechanism for data transfer between USB devices with a line/bus speed up to 480 Mbps. The device USB subsystem has two independent USB 2.0 Modules built around two OTG controllers. The OTG supplement feature, the support for a dynamic role change, is also supported. Each port has the support for a dual-role feature allowing for additional versatility enabling operation capability as a host or peripheral. Both ports have identical capabilities and operate independent of each other.

Each USB controller is built around the Mentor USB OTG controller (musbmhdc) and TI PHY. Each USB controller has user configurable 32K Bytes of Endpoint FIFO and has the support for 15 'Transmit' endpoints and 15 'Receive' endpoints in addition to Endpoint 0. The USB subsystem makes use of the CPPI 4.1 DMA for accelerating data movement via a dedicated DMA hardware.

The two USB modules share the CPPI DMA controller and accompanying Queue Manager, Interrupt Pacer, Power Management module, and PHY/UTMI clock.

Within the descriptions of the USB subsystem that would follow, the term USB controller or USB PHY is used to mean/refer to any of the two USB controllers or PHYs existing within the USB subsystem. The term USB module is used to mean/refer to any of the two USB modules. USB0 is used to refer to one of the USB modules and USB1 is used to refer to the other USB module.

### 16.1.1 Acronyms, Abbreviations, and Definitions

AHB	Advanced High-performance Bus
CBA	Common Bus Architecture
CDC	Change Data Capture
CPPI	Communications Port Programming Interface
CPU	Central Processing Unit
DFT	Design for Test
DMA	Direct Memory Access
DV	Design Verification
EOI	End of Interrupt
EOP	End of Packet
FIFO	First-In First-Out
FS	Full-Speed USB data rate
HNP	Host Negotiation
HS	High-Speed USB data rate
INTD	Interrupt Distributor
IP	Intellectual Property
ISO	Isochronous transfer type
LS	Low-Speed USB data rate
MHz	Megahertz
MOP	Middle of Packet
OCP	Open Core Protocol
OCP HD	OCP High Performance
OCP MMR	OCP Memory Mapped Registers
OTG	On-The-Go
PDR	Physical Design Requirements
PHY	Physical Layer Device
PPU	Packet Processing Unit
RAM	Random Access Memory
RNDIS	Remote Network Driver Interface Specification

RX	Receive
SCR	Switched Central Resource
SOC	System On a Chip
SOP	Start of Packet
SRP	Session Resume
TX	Transmit
USB	Universal Serial Bus
USB0	One of the two USB 2.0 Compliant USB Module
USB1	One of the two USB2.0 Compliant USB Module
USBSS	USB Subsystem (contains USB0 and USB1)
UTMI	USB 2.0 Transceiver Macrocell Interface
XDMA	Transfer DMA (DMA other than CPPI DMA used within the Controller)

### 16.1.2 USB Features

The main features of the USB subsystem are:

- Contains 2 usb20otg\_f controller modules with the following features:
  - Built around the Mentor USB 2.0 OTG core (musbmhdc)
  - Supports USB 2.0 peripheral at speeds HS (480 Mb/s) and FS (12 Mb/s)
  - Supports USB 2.0 host or OTG at speeds HS (480 Mb/s), FS (12 Mb/s), and LS (1.5 Mb/s)
  - Supports all modes of transfers (control, bulk, interrupt, and isochronous)
  - Supports high bandwidth ISO mode
  - Supports 16 Transmit (TX) and 16 Receive (RX) endpoints including endpoint 0
  - Supports USB OTG extensions for Session Resume (SRP) and Host Negotiation (HNP)
  - Includes a 32K endpoint FIFO RAM, and supports programmable FIFO sizes
  - Includes RNDIS mode for accelerating RNDIS type protocols using short packet termination over USB
  - Includes CDC Linux mode for accelerating CDC type protocols using short packet termination over USB
  - Includes an RNDIS like mode for terminating RNDIS type protocols without using short packet termination for support of MSC applications
- Includes two USB2.0 OTG PHYs
- Interfaces to the CPU via 3 OCP interfaces:
  - Master OCP HP interface for the DMA
  - Master OCP HP interface for the Queue manager
  - Slave OCP MMR interface
- Includes a CPPI 4.1 compliant DMA controller sub-module with 30 RX and 30 TX simultaneous data connections
- Includes a CPPI 4.1 DMA scheduler
- DMA supports CPPI host descriptor formats
- DMA supports stall on buffer starvation
- Supports data buffer sizes up to 4M bytes
- CPPI FIFO interface per TX/RX endpoint
- Provides a CPPI Queue Manager module with 92 queues for queuing/de-queuing packets.
- DMA pacing logic for interrupts
- Loopback MGC test using the UTMI interfaces

---

### **16.1.3 Unsupported USB OTG and PHY Features**

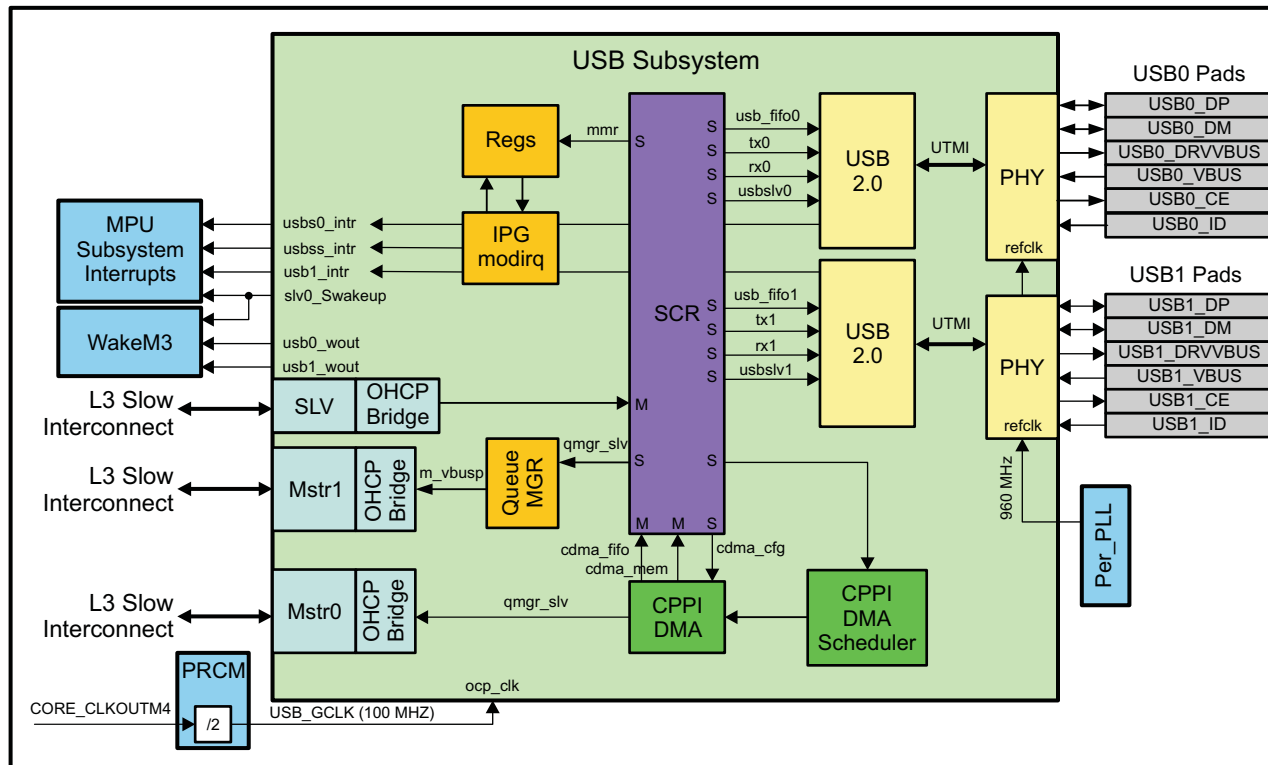

This device supports USBOTG module host, device and OTG features.

## 16.2 Integration

This device implements the USB2.0 OTG dual port module and PHY for interfacing to USB as a peripheral or host.

Figure 16-1 shows the integration of the USB module on this device.

Figure 16-1. USB Integration

### 16.2.1 USB Connectivity Attributes

The USB module itself has a very large number of interrupt outputs. For ease of integration, these outputs are all routed to a pair of interrupt aggregators. These aggregator blocks generate a single interrupt on the first occurrence of any interrupt from the USB or DMA logic of the module.

Table 16-1. USB Connectivity Attributes

Attributes	Type
Power domain	Peripheral Domain
Clock domain	PD_PER_L3_GCLK (OCP) CLKDCOLDO (PHY)
Reset signals	DEF_DOM_RST_N USB_POR_N
Idle/Wakeup signals	Smart idle Wakeup Standby

**Table 16-1. USB Connectivity Attributes (continued)**

Attributes	Type
Interrupt request	4 interrupts usbss (USBSSINT) to MPU subsystem usb0 (USBINT0) to MPU subsystem usb1 (USBINT1) to MPU subsystem slv0p_Swakeup (USBWAKEUP) to MPU subsystem and WakeM3 2 Wakeup Events to WakeM3 usb0_wuout usb1_wuout
DMA request	None
Physical address	L3 Slow slave port

### 16.2.2 USB Clock and Reset Management

Each USB controller has a PHY module that generates the UTMI clock. The UTMI clock is fixed in the UTMI specification for an 8-bit interface at 60 MHz (480 Mb/s). The PHYs require a low-jitter 960-MHz source clock.

**Table 16-2. USB Clock Signals**

Clock Signal	Max Freq	Reference / Source	Comments
ocp_clk OCP / Functional clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l3s_gclk From PRCM
phy0_other_refclk960m Phy reference clock	960 MHz	CLKDCOLDO	clkdcoldo_po From Per PLL
phy1_other_refclk960m Phy reference clock	960 MHz	CLKDCOLDO	clkdcoldo_po From Per PLL

### 16.2.3 USB Pin List

The USB external interface signals are shown in [Table 16-3](#).

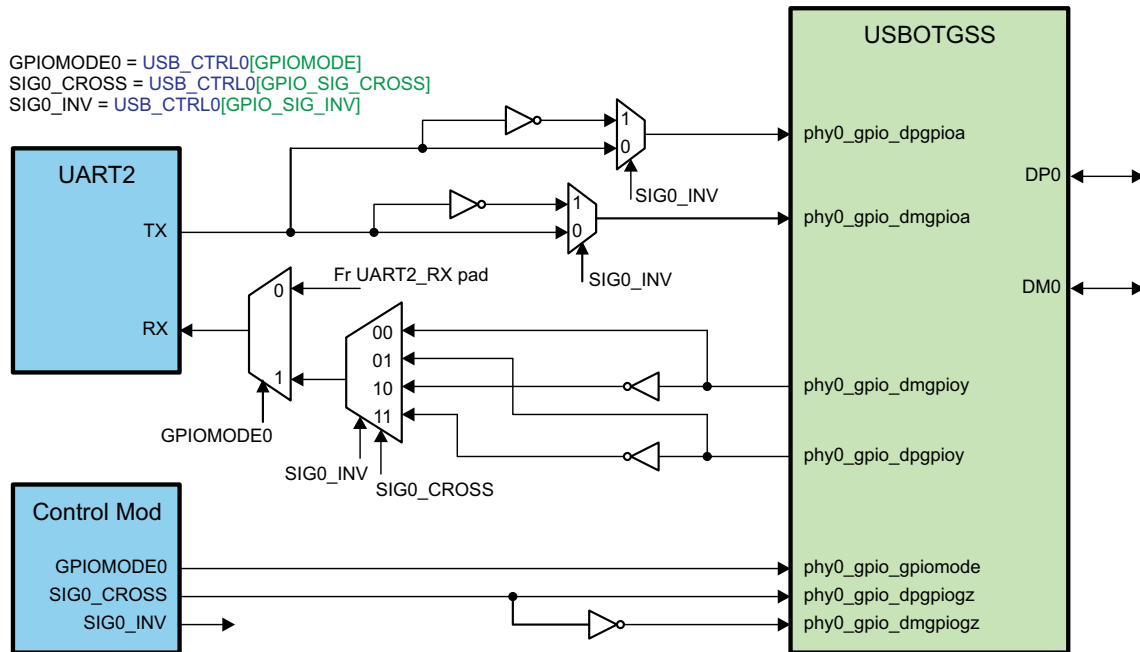

**Table 16-3. USB Pin List**

Pin	Type		Description
USBx_DP <sup>(1)</sup>	USB	Analog I/O	USBx data differential pair
USBx_DM <sup>(1)</sup>	GPIO	Digital I/O	
USBx_DRVVBUS	Digital output		USBx VBUS supply control
USBx_VBUS	Analog input		USBx VBUS (input only for voltage sensing)
USBx_ID	Analog input		USBx OTG identification
USBx_CE	Digital output		USBx Phy charge enable

<sup>(1)</sup> Analog in USB mode; CMOS in GPIO mode.

### 16.2.4 USB GPIO Details

The USB module supports configuration of the DP and DM pins as pass-through GPIOs. In this device, the GPIO mode is used to provide UART over USB interface functionality. Chip level logic allows connection of the UART TX/RX data signals to either DP or DM in either normal or inverted state as shown in [Figure 16-2](#). The diagram shows the UART2 / USB0 port implementation. This logic is also replicated for the UART3 / USB1 ports.

**Figure 16-2. USB GPIO Integration**

### 16.2.5 USB Unbonded PHY Pads

The USBOTGSS includes two USB PHY modules. On packages where only 1 PHY is bonded out to pins (e.g. 13x13 package), the following procedures must be followed in order to ensure that the unbonded PHY pads do not cause issues with USBOTGSS operation:

- The USB Controller corresponding to the unbonded PHY must be placed in Host Mode by setting Bit2 of the USB Core DEVCTL register.
- The unbonded PHY must be placed in the SUSPEND state by setting Bits[1:0] of the USB Core POWER register.
- The Control Module USB\_CTRLx register corresponding to the unbonded PHY must have the following bits programmed as shown:
  - CHGDET\_DIS = 1
  - CM\_PWRDN = 1
  - GPIOMODE = 0

## 16.3 Functional Description

The USB controller within the device supports 15 Transmit endpoints and 15 Receive endpoints in addition to Endpoint 0. (The use of these endpoints for IN and OUT transactions depends on whether the USB controller is being used as a device/peripheral or as a host. When used as a peripheral, IN transactions are processed through TX endpoints and OUT transactions are processed through Rx endpoints. When used as a host, IN transactions is processed through Rx endpoints and OUT transactions is processed through TX endpoints.)

These additional endpoints can be individually configured in software to handle either Bulk transfers (which also allows them to handle Interrupt transfers), Isochronous transfers or Control transfers. Further, the endpoints can also be allocated to different target device functions on the fly – maximizing the number of devices that can be simultaneously supported.

Each endpoint requires a chunk of memory allocated within the FIFO to be associated with it. The USB module has a single block of FIFO RAM (32 Kbytes in size) to be shared by all endpoints. The FIFO for Endpoint 0 is required to be 64 bytes deep and will buffer 1 packet. The first 64 Bytes of the FIFO RAM is reserved by hardware for Endpoint 0 usage and for this reason user software does not need (nor has the capability) to allocate FIFO for Endpoint 0. The rest of the FIFO RAM is user configurable with regard to the other endpoint FIFOs, which may be from 8 to 8192 bytes in size and can buffer either 1 or 2 packets.

Separate FIFOs may be associated with each endpoint: alternatively a TX endpoint and the Rx endpoint with the same Endpoint number can be configured to use the same FIFO, for example to reduce the size of RAM block needed, provided they can never be active at the same time.

The role (host or device) that the USB controller assumes is chosen by user firmware programming the respective USB controller MODE register defined within the USB subsystem space. Note that some USB pins have not been bonded out and the functions of these pins are controlled by user software via dedicated registers.

The user has access to the controller through the OCP slave interface via the CPU. The user can process USB transactions entirely from the CPU or can also use the DMA to perform data transfer. The CPPI DMA can be used to service Endpoints 1 to 15 not Endpoint 0. CPU access method is used to service Endpoint 0 transactions.

### 16.3.1 VBUS Voltage Sourcing Control

When any of the USB controllers assumes the role of a host, the USB is required to supply a 5V power source to an attached device through its VBUS line. In order to achieve this task, the USB controller requires the use of an external power logic (or charge pump) capable of sourcing 5V power. A USB\_DRVVBUS is used as a control signal to enable/disable this external power logic to either source or disable power on the VBUS line. The control on the USB\_DRVVBUS is automatic and is handled by the USB controller. The control should be transparent to the user so long as the proper hardware connection and software initialization are in place. The USB controller drives the USB\_DRVVBUS signal high when it assumes the role of a host while the controller is in session. When assuming the role of a device, the controller drives the USB\_DRVVBUS signal low disabling the external charge pump/power logic; hence, no power is driven on the VBUS line (in this case, power is expected to be sourced by the external host).

Note that both USBs are self-powered and the device does not rely on the voltage on the VBUS line sourced by an external host for controller operation when assuming the role of a device. The power on the VBUS is used to identify the presence of a Host. It is also used to power up the pull-up on the D+ line. The USB PHY would continually monitor the voltage on the VBUS and report the status to USB controller.

### 16.3.2 Pullup/PullDown Resistors

Since the USB controllers are dual role controllers, capable of assuming a role of a host or device, the necessary required pull-up/pull-down resistors can not exist external to the device. These pull-up/pull-down resistors exist internal to the device, within the PHY to be more specific, and are enabled and disabled based on the role the controller assumes allowing dynamic hardware configuration.

When assuming the role of a host, the data lines are pulled low by the PHY enabling the internal 15KOhms resistors. When assuming the role of a device the required 1.5Kohm pull-up resistor on the D+ line is enabled automatically to signify the USB capability to the external host as a FS device (HS operation is negotiated during reset bus condition).

### 16.3.3 Role Assuming Method

For an OTG controller, the usual method followed by the controller to assume the role of a host or a device is governed by the state of the ID pin which in turn is controlled by the USB cable connector type. The device has bonded out these ID pins and allows the control to be handled directly from the connector, i.e. the USB controller would assume the role based on the cable end inserted to the mini or micro A/B connector. An alternate method where the ID pin signal is bypassed and the firmware controls the role the controller assumes exists via register access allowing additional control for systems that do not require the use of the USB ID pin. In this case the USBnMODE [Bit7=IDDIG\_MUX] needs to be programmed with a value of 1 so that Register programming will be used.

Two registers, USB0 Mode Register at offset 10E8h and USB1 Mode Register at offset 18E8h, are used for a user to select the role the USB controller assumes. The user is required to program the corresponding register prior to the USB controller is in session.

### 16.3.4 Clock, PLL, and PHY Initialization

Prior to configuring the USB Module Registers, the USB SubSystem and PHY are required to be released from reset, enable interconnects and controllers clocks as well as configure the USB PHY with appropriate setting. Not all registers related for this task are captured within this document. Please refer to the PRCM for clocking and Control Module for PHY configuration registers definitions.

### 16.3.5 Indexed and Non-Indexed Register Spaces

The USB controller provides two mechanisms for accessing endpoint control and status registers; Indexed and Non-Indexed method.

**Indexed Endpoint Control/Status Register Space.** This register space can be thought of as a region populated with Proxy Registers. This register space is a memory-mapped region at offset 1410h to 141Fh for USB0 and 1C10h to 1C1Fh for USB1. The endpoint register space mapped at this region is selected by programming the corresponding INDEX register (@ offsets 140Eh and 1C0Eh for USB0 and USB1 respectively) of the controller.

By programming the INDEX register with the corresponding endpoint number, the control and status register corresponding to that particular endpoint is accessible from this Indexed Region. In other words, Index Register region behaves as a proxy to access a selected endpoint registers.

**Non-indexed Endpoint Control/Status Register Space.** These regions are dedicated endpoint registers memory-mapped residing at offsets 1500h to 16FFh for USB0 and 1D00h to 1EFFh for USB1. Registers at offset 1500h to 150Fh belong to Endpoint 0; registers at offset 1510h to 151Fh belong to Endpoint 1... and lastly registers at offset 16F0h to 16FFh belong to Endpoint 15 for USB0. Similarly registers at offset 1D00h to 1E0Fh belong to Endpoint 0; registers at offset 1D10h to 1D1Fh belong to Endpoint 1... and finally registers at offset 1DF0h to 1DFFh belong to Endpoint 15 for USB1.

This allows the user/firmware to access an endpoint register region directly from its unique space, as specified within a non-indexed region or from a proxy space by programming the corresponding Index register.

Note: The control and status registers/regions apply to both Tx and Rx of a given Endpoint. That is, Endpoint 1 Tx and Endpoint 1 Rx registers occupy the same register space.

For detailed information about the USB controller registers, see [Section 16.5](#).

### 16.3.6 Dynamic FIFO Sizing

Each USB module supports a total of 32K bytes of FIFO RAM to dynamically allocate FIFO to all endpoints in use. Each endpoint requires a FIFO to be associated with it. There is one set of register per endpoint available for FIFO allocation, excluding endpoint 0. FIFO configuration registers are Indexed registers and cannot be accessed directly; configuration takes place via accessing proxy registers. The INDEX register at addresses 140Eh or 1C0Eh must be set to the appropriate endpoint. In other words, the Endpoint FIFO configuration registers do not have non-indexed regions.

The allocation of FIFO space to the different endpoints requires programming for each Tx and Rx endpoint with the following information:

- The start address of the FIFO within the RAM block
- The maximum size of packet to be supported
- Whether double-buffering is required

(These last two together define the amount of space that needs to be allocated to the FIFO.)

It is the responsibility of the firmware to ensure that all the Tx and Rx endpoints (other than endpoint 0) that are active in the current USB configuration have a block of FIFO RAM allocated for their use. The maximum FIFO size for endpoint 0 required is 64 bytes deep and which is large enough to buffer one packet. For this reason, the first 64 bytes of FIFO memory is reserved for Endpoint 0 usage and this resource allocation is implied to be available at all times and no FIFO allocation is required for Endpoint 0. For endpoints other than endpoint 0, the FIFO RAM interface is configurable and must have a minimum size of 8 bytes and should be capable of buffering either 1 or 2 packets. Separate FIFOs may be associated with each endpoint: alternatively a Tx endpoint and the Rx endpoint with the same Endpoint number can be configured to use the same FIFO, to reduce the size of RAM block needed, provided they can never be active at the same time.

**NOTE:** The option of dynamically setting FIFO sizes only applies to Endpoints 1-15. Endpoint 0 FIFO has a fixed size (64 bytes) and a fixed location which is the first 64 Bytes of FIFO (FIFO addresses 0-63).

### 16.3.7 USB Controller Host and Peripheral Modes Operation

The two USB modules can be used in a range of different environments. They can be used as either a high-speed or a full-speed USB peripheral device attached to a conventional USB host (such as a PC) in a point-to-point type of arrangement. As a host, the USB modules can also be used with another peripheral device of any speed (high-,full-, or low-speed) in a point-to-point arrangement or can be used as the host to a range of peripheral devices in a multi-point setup; one-to-many via hub. Note that the role each USB controller is assuming is independent of each other. Two options (h/w or s/w) exist for a USB role assumption/configuration.

For a USB Peripheral configuration the user has the option of using the cable end to select the role by attaching the mini or micro b side of the cable (can consider this as a h/w option) or use the optional method where the firmware is required to program the respective USB Mode Register IDDIG bit field with a value of '1' prior to the USB controller goes into session (can consider this as a s/w option).

Similarly, for a USB host configuration the user has the option of using the cable end to select the role by attaching the mini or micro a side of the cable (can consider this as a h/w option) or use the optional method where the firmware is required to program the respective USB Mode Register IDDIG bit field with a value of '0' value prior to the USB controller going into session (can consider this as a s/w option).

When using the s/w option, the USB ID pin state is ignored/bypassed (this is a similar configuration where an ID pin does not exist) and the USB2.0 controller role adaptation of a host or peripheral (device) is dependent upon the state of the respective USB Mode Register IDDIG field. If the IDDIG field is programmed by the user with a value of '1' prior to the USB going into session, it would assume the role of a peripheral/device. However, if the IDDIG field is programmed with the value of '0', the USB controller will assume the role of a host. What this means is that the USB cable end, connector, will not be able to control the role of the OTG controller and the user needs to be aware of the firmware program setting prior to performing a USB connection.

The procedure for the USB2.0 OTG controller determining its operating modes (usb controller assuming a role of a host or a peripheral) starts when the USB 2.0 controller goes into a session. The USB 2.0 controller is in session when either it senses a voltage ( $\geq 4.4V$ ) on the USBx\_VBUSIN pin and the controller sets its DEVCTL[SESSION] bit field or when the firmware sets the DEVCTL[SESSION] bit; assuming that it will operating as a host.

When the DEVCTL[SESSION] bit is set, the controller will start sensing the state of the Iddig signal, which in turn is controlled either by the USBx\_ID pin (h/w option) or by the IDDIG bit field of the MODE Register (s/w option). If the state of the iddig signal is found to be low (IDDIG is programmed with '0') then the USB2.0 controller will assume the role of a host and when it finds the iddig signal to be high (IDDIG is programmed with '1') then it will assume the role of a device. Note that iddig is an internal signal that could be driven to high or low via firmware from dedicated registers.

Upon the USB controller determining its role as a host, it will drive the USBx\_DRVVBUS pin high to enable the external power logic so that it start sourcing the required 5V power (must be  $\geq 4.4V$  but to account for the voltage drop on the cable it is suggested to be in the neighborhood of 4.75V). The USB2.0 controller will then wait to for the voltage of the USBx\_VBUSIN to go high. After 100 ms, if it does not see the voltage on the USBX\_VBUSIN pin to be within a Vbus Valid range ( $\geq 4.4V$ ), it will generate a Vbus error interrupt. Assuming that the voltage level of the USBX\_VBUSIN is found to within the Vbus Valid range, the USB 2.0 host controller will wait for a device to connect; that is for it to see one of its data lines USB0/1\_DP/DM be pulled high.

When assuming the role of a peripheral, assuming that the firmware has set the POWER[SOFTCONN] bit, and the USBx\_ID pin is floating (h/w option) or USBx Mode Register IDDIG bit field is programmed with '1' (s/w option) and an external host is sourcing power on the USBx\_VBUSIN line then the USB2.0 controller will set the DEVCTL[SESSION] bit instructing the controller to go into session. Not that the voltage on the USBx\_VBUSIN pin must be within Vbus Valid range (i.e. greater or equal to 4.4V). When the controller goes into session, it will force the USB2.0 Controller to sense the state of the iddig signal. Once it senses iddig signal to be high, it will enable its 1.5Kohm pull-up resistor to signify the external host that it is a Full-Speed device. Note that even when operating as a High-Speed peripheral; the USB controller has to first come up as Full-Speed and then later transition to High-Speed. The USB2.0 controller will then waits for a reset signal from the external host. Then after, if High-Speed option has been selected it will negotiate for a High-Speed operation and if its request has been accepted by the host, it will enable its precision 45ohm termination resistors (to stop signal reflection) on its data lines and disable the 1.5Kohm resistor.

### 16.3.8 Protocol Description(s)

This section describes the implementation of the USB protocol(s) by the USB modules.

#### 16.3.8.1 USB Controller Peripheral Mode Operation

The USB controller assumes the role of a peripheral when the USBx\_ID pin is floating or USB Mode Register[iddig=bit8] is set to 1 (provided that iddig\_mux, which is bit7 of USBnMODE is also set to 1) by the user application prior to the controller goes into session. When the USB controller go into session it will assume the role of a device.

**Soft connect** –After a POR or USB Module soft reset, the SOFTCONN bit of POWER register (bit 6) is cleared to 0. The controller will therefore appear disconnected until the software has set the SOFTCONN bit to 1. The application software can then choose when to set the PHY into its normal mode. Systems with a lengthy initialization procedure may use this to ensure that initialization is complete and the system is ready to perform enumeration before connecting to the USB. Once the SOFTCONN bit has been set, the software can also simulate a disconnect by clearing this bit to 0.

**Entry into suspend mode** –When operating as a peripheral device, the controller monitors activity on the bus and when no activity has occurred for 3 ms, it goes into Suspend mode. If the Suspend interrupt has been enabled, an interrupt will be generated at this time.

At this point, the controller can then be left active (and hence able to detect when Resume signaling occurs on the USB), or the application may arrange to disable the controller by stopping its clock. However, the controller will not then be able to detect Resume signaling on the USB if clocks are not running. If such is the case, external hardware will be needed to detect Resume signaling (by monitoring the DM and DP signals), so that the clock to the controller can be restarted.

**Resume Signaling** –When resume signaling occurs on the bus, first the clock to the controller must be restarted if necessary. Then the controller will automatically exit Suspend mode. If the Resume interrupt is enabled, an interrupt will be generated.

**Initiating a remote wakeup** –If the software wants to initiate a remote wakeup while the controller is in Suspend mode, it should set the POWER[RESUME] bit to 1. The software should leave then this bit set for approximately 10 ms (minimum of 2 ms, a maximum of 15 ms) before resetting it to 0.

**NOTE:** No resume interrupt will be generated when the software initiates a remote wakeup.

**Reset Signaling** –When reset signaling or bus condition occurs on the bus, the controller performs the following actions:

- Clears FADDR register to 0
- Clears INDEX register to 0
- Flushes all endpoint FIFOs
- Clears all controller control/status registers
- Generates a reset interrupt
- Enables all interrupts at the core level.

If the HSENA bit within the POWER register (bit 5) is set, the controller also tries to negotiate for high-speed operation. Whether high-speed operation is selected is indicated by HSMODE bit of POWER register (bit 4). When the application software receives a reset interrupt, it should close any open pipes and wait for bus enumeration to begin.

##### 16.3.8.1.1 Control Transactions:Peripheral Mode

Endpoint 0 is the main control endpoint of the core. The software is required to handle all the standard device requests that may be sent or received via endpoint 0. These are described in Universal Serial Bus Specification, Revision 2.0, Chapter 9. The protocol for these device requests involves different numbers and types of transactions per request/command. To accommodate this, the software needs to take a state machine approach to command decoding and handling.

The Standard Device Requests received by a USB peripheral device can be divided into three categories: Zero Data Requests (in which all the information is included in the command; no additional data is required), Write Requests (in which the command will be followed by additional data), and Read Requests (in which the device is required to send data back to the host).

This section looks at the sequence of actions that the software must perform to process these different types of device request.

**NOTE:** The Setup packet associated with any standard device request should include an 8-byte command. Any setup packet containing a command field other than 8 bytes will be automatically rejected by the controller.

#### 16.3.8.1.1.1 Zero Data Requests: Peripheral Mode

Zero data requests have all their information included in the 8-byte command and require no additional data to be transferred. Examples of Zero Data standard device requests are:

- SET\_FEATURE
- CLEAR\_FEATURE
- SET\_ADDRESS
- SET\_CONFIGURATION
- SET\_INTERFACE

The sequence of events will begin, as with all requests, when the software receives an endpoint 0 interrupt. The RXPKTRDY bit of PERI\_CSR0 (bit 0) will also have been set. The 8-byte command should then be read from the endpoint 0 FIFO, decoded and the appropriate action taken.

For example, if the command is SET\_ADDRESS, the 7-bit address value contained in the command should be written to the FADDR register at the completion of the command. The PERI\_CSR0 register should be written by setting the SERV\_RXPKTRDY bit (bit 6) (indicating that the command has been read from the FIFO) and also setting the DATAEND bit (bit 3) (indicating that no further data is expected for this request). The interval between setting SERV\_RXPKTRDY bit and DATAEND bit should be very small to avoid getting a SETUPEND error condition. It is highly recommended to set both bits at the same time.

When the host moves to the status stage of the request, a second endpoint 0 interrupt will be generated to indicate that the request has completed. No further action is required from the software. The second interrupt is just a confirmation that the request completed successfully. For SET\_ADDRESS command, the address should be written to FADDR register at the completion of the command, i.e. when the status stage interrupt is received.

If the command is an unrecognized command, or for some other reason cannot be executed, then when it has been decoded, the PERI\_CSR0 register should be written to set the SERV\_RXPKTRDY bit (bit 6) and to set the SENDSTALL bit (bit 5). When the host moves to the status stage of the request, the controller will send a STALL packet telling the host that the request was not executed. A second endpoint 0 interrupt will be generated and the SENTSTALL bit (bit 2 of PERI\_CSR0) will be set.

If the host sends more data after the DATAEND bit has been set, then the controller will send a STALL packet automatically. An endpoint 0 interrupt will be generated and the SENTSTALL bit (bit 2 of PERI\_CSR0) will be set.

**NOTE:** DMA is not supported for endpoint 0; endpoint 0 is always serviced via CPU.

#### 16.3.8.1.1.2 Write Requests: Peripheral Mode

Write requests involve an additional packet (or packets) of data being sent from the host after the 8-byte command. An example of a Write standard device request is: SET\_DESCRIPTOR.

The sequence of events will begin, as with all requests, when the software receives an endpoint 0 interrupt. The RXPKTRDY bit of PERI\_CSR0 will also have been set. The 8-byte command should then be read from the Endpoint 0 FIFO and decoded.

As with a zero data request, the PERI\_CSR0 register should then be written to set the SERV\_RXPKTRDY bit (bit 6) (indicating that the command has been read from the FIFO) but in this case the DATAEND bit (bit 3) should not be set (indicating that more data is expected).

When a second endpoint 0 interrupt is received, the PERI\_CSR0 register should be read to check the endpoint status. The RXPKTRDY bit of PERI\_CSR0 should be set to indicate that a data packet has been received. The COUNT0 register should then be read to determine the size of this data packet. The data packet can then be read from the endpoint 0 FIFO.

If the length of the data associated with the request (indicated by the wLength field in the command) is greater than the maximum packet size for endpoint 0, further data packets will be sent. In this case, PERI\_CSR0 should be written to set the SERV\_RXPKTRDY bit, but the DATAEND bit should not be set.

When all the expected data packets have been received, the PERI\_CSR0 register should be written to set the SERV\_RXPKTRDY bit and to set the DATAEND bit (indicating that no more data is expected).

When the host moves to the status stage of the request, another endpoint 0 interrupt will be generated to indicate that the request has completed. No further action is required from the software, the interrupt is just a confirmation that the request completed successfully.

If the command is an unrecognized command, or for some other reason cannot be executed, then when it has been decoded, the PERI\_CSR0 register should be written to set the SERV\_RXPKTRDY bit (bit 6) and to set the SENDSTALL bit (bit 5). When the host sends more data, the controller will send a STALL to tell the host that the request was not executed. An endpoint 0 interrupt will be generated and the SENTSTALL bit of PERI\_CSR0 (bit 2) will be set.

If the host sends more data after the DATAEND has been set, then the controller will send a STALL. An endpoint 0 interrupt will be generated and the SENTSTALL bit of PERI\_CSR0 (bit 2) will be set.

#### 16.3.8.1.1.3 Read Requests: Peripheral Mode

Read requests have a packet (or packets) of data sent from the function to the host after the 8-byte command. Examples of Read Standard Device Requests are:

- GET\_CONFIGURATION
- GET\_INTERFACE
- GET\_DESCRIPTOR
- GET\_STATUS
- SYNCH\_FRAME

The sequence of events will begin, as with all requests, when the software receives an endpoint 0 interrupt. The RXPKTRDY bit of PERI\_CSR0 (bit 0) will also have been set. The 8-byte command should then be read from the endpoint 0 FIFO and decoded. The PERI\_CSR0 register should then be written to set the SERV\_RXPKTRDY bit (bit 6) (indicating that the command has read from the FIFO).

The data to be sent to the host should then be written to the endpoint 0 FIFO. If the data to be sent is greater than the maximum packet size for endpoint 0, only the maximum packet size should be written to the FIFO. The PERI\_CSR0 register should then be written to set the TXPKTRDY bit (bit 1) (indicating that there is a packet in the FIFO to be sent). When the packet has been sent to the host, another endpoint 0 interrupt will be generated and the next data packet can be written to the FIFO.

When the last data packet has been written to the FIFO, the PERI\_CSR0 register should be written to set the TXPKTRDY bit and to set the DATAEND bit (bit 3) (indicating that there is no more data after this packet).

When the host moves to the status stage of the request, another endpoint 0 interrupt will be generated to indicate that the request has completed. No further action is required from the software: the interrupt is just a confirmation that the request completed successfully.

If the command is an unrecognized command, or for some other reason cannot be executed, then when it has been decoded, the PERI\_CSR0 register should be written to set the SERV\_RXPKTRDY bit (bit 6) and to set the SENDSTALL bit (bit 5). When the host requests data, the controller will send a STALL to tell the host that the request was not executed. An endpoint 0 interrupt will be generated and the SENTSTALL bit of PERI\_CSR0 (bit 2) will be set.

If the host requests more data after DATAEND (bit 3) has been set, then the controller will send a STALL. An endpoint 0 interrupt will be generated and the SENTSTALL bit of PERI\_CSR0 (bit 2) will be set.

#### 16.3.8.1.1.4 Endpoint 0 States: Peripheral Mode

When the USB controller is operating as a peripheral device, the endpoint 0 control needs three modes – IDLE, TX and RX – corresponding to the different phases of the control transfer and the states endpoint 0 enters for the different phases of the transfer (described in later sections).

The default mode on power-up or reset should be IDLE. RXPkTRDY bit of PERI\_CSR0 (bit 0) becoming set when endpoint 0 is in IDLE state indicates a new device request. Once the device request is unloaded from the FIFO, the controller decodes the descriptor to find whether there is a data phase and, if so, the direction of the data phase of the control transfer (in order to set the FIFO direction). See [Figure 16-3](#).

Depending on the direction of the data phase, endpoint 0 goes into either TX state or RX state. If there is no Data phase, endpoint 0 remains in IDLE state to accept the next device request

The actions that the CPU needs to take at the different phases of the possible transfers (for example, loading the FIFO, setting TXPKTRDY) are indicated in [Figure 16-4](#).

**Figure 16-3. CPU Actions at Transfer Phases**

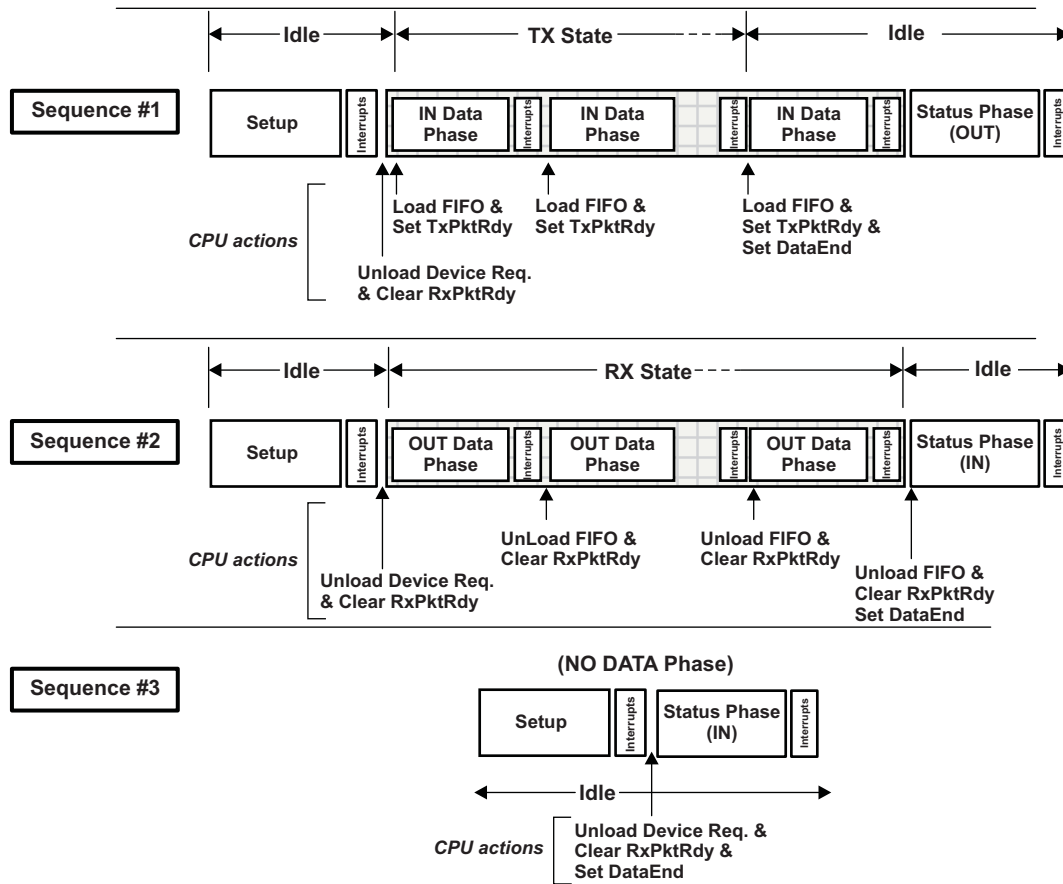

Figure 16-4. Sequence of Transfer

#### 16.3.8.1.1.4.1 Endpoint 0 Interrupt Generating Events: Peripheral Mode

An Endpoint 0 interrupt is generated when any of the below events occur and Interrupt Service handler should determine the right event and launch the proper handler

The following events will cause Endpoint 0 Interrupt to be generated while the controller is operating assuming the role of a device/peripheral:

- The controller sets the RXPKTRDY bit of PERI\_CSR0 (bit 0) after a valid token has been received and data has been written to the FIFO (legal status condition).
- The controller clears the TXPKTRDY bit of PERI\_CSR0 (bit 1) after the packet of data in the FIFO has been successfully transmitted to the host (legal status condition).
- The controller sets the SENTSTALL bit of PERI\_CSR0 (bit 2) after a control transaction is ended due to a protocol violation (illegal status condition).
- The controller sets the SETUPEND bit of PERI\_CSR0 (bit 4) because a control transfer has ended before DATAEND (bit 3 of PERI\_CSR0) is set (illegal status condition).

In order to determine the cause of the interrupt, the detail below recommends the order of cause determination and execution.

Whenever the endpoint 0 service routine is entered, the software must first check to see if the current control transfer has been ended due to either a STALL condition or a premature end of control transfer. If the control transfer ends due to a STALL condition, the SENTSTALL bit would be set. If the control transfer ends due to a premature end of control transfer, the SETUPEND bit would be set. In either case, the software should abort processing the current control transfer and set the state to IDLE.

Once the software has determined that the interrupt was not generated by an illegal bus state, the next action taken depends on the endpoint state.

If endpoint 0 is in IDLE state, the only valid reason an interrupt can be generated is as a result of the controller receiving data from the bus. The service routine must check for this by testing the RXPKTRDY bit of PERI\_CSR0 (bit 0). If this bit is set, then the controller has received a SETUP packet. This must be unloaded from the FIFO and decoded to determine the action the controller must take. Depending on the command contained within the SETUP packet, endpoint 0 will enter one of three states:

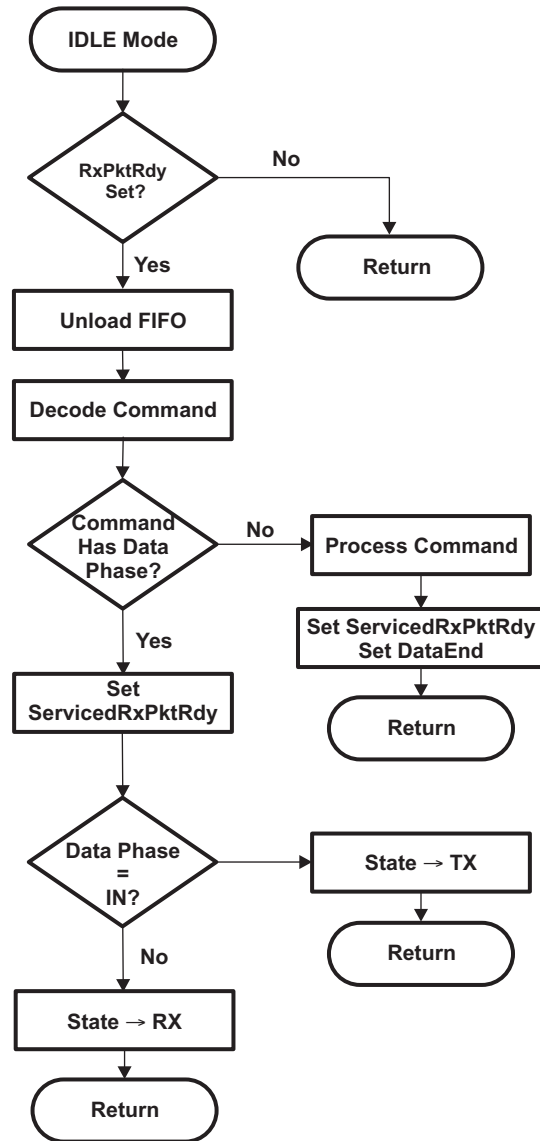

- If the command is a single packet transaction (SET\_ADDRESS, SET\_INTERFACE etc.) without any data phase, the endpoint will remain in IDLE state.
- If the command has an OUT data phase (SET\_DESCRIPTOR etc.), the endpoint will enter RX state.
- If the command has an IN data phase (GET\_DESCRIPTOR etc.), the endpoint will enter TX state.
- If the endpoint 0 is in TX state, the interrupt indicates that the core has received an IN token and data from the FIFO has been sent. The software must respond to this either by placing more data in the FIFO if the host is still expecting more data or by setting the DATAEND bit to indicate that the data phase is complete. Once the data phase of the transaction has been completed, endpoint 0 should be returned to IDLE state to await the next control transaction (status stage).
- If the endpoint is in RX state, the interrupt indicates that a data packet has been received. The software must respond by unloading the received data from the FIFO. The software must then determine whether it has received all of the expected data. If it has, the software should set the DATAEND bit and return endpoint 0 to IDLE state. If more data is expected, the firmware should set the SERV\_RXPKTRDY bit of PERI\_CSR0 (bit 6) to indicate that it has read the data in the FIFO and leave the endpoint in RX state.

**16.3.8.1.1.4.2 Idle Mode: Control Transfer of Peripheral Mode**

IDLE mode is the mode the Endpoint 0 control needs to select at power-on or reset and is the mode to which the Endpoint 0 control should return when the RX and TX modes are terminated.

It is also the mode in which the SETUP phase of control transfer is handled (as outlined in [Figure 16-5](#)).

**Figure 16-5. Flow Chart of Setup Stage of a Control Transfer in Peripheral Mode**

### 16.3.8.1.1.4.3 TX Mode: Control Transfer of Peripheral Mode

When the endpoint is in TX state, all arriving IN tokens need to be treated as part of a data phase until the required amount of data has been sent to the host. If either a SETUP or an OUT token is received while the endpoint is in the TX state, this will cause a SETUPEND condition to occur as the core expects only IN tokens.

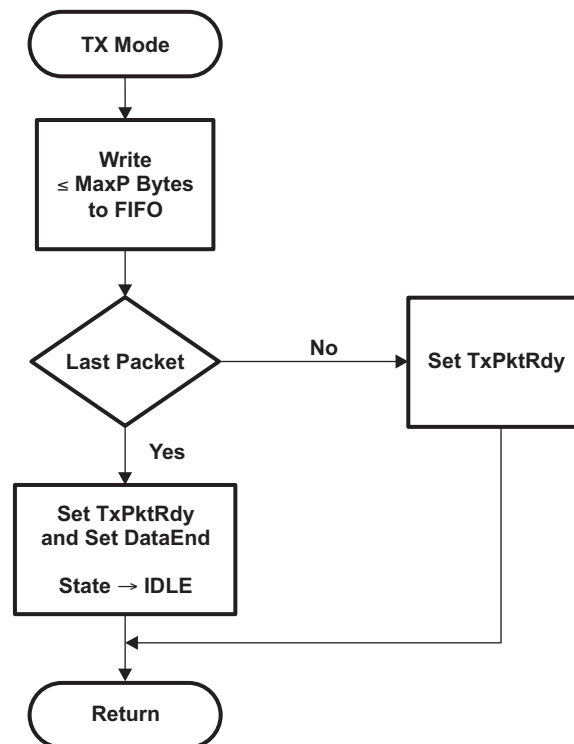

Three events can cause TX mode to be terminated before the expected amount of data has been sent as shown in Figure 16-6:

1. The host sends an invalid token causing a SETUPEND condition (bit 4 of PERI\_CSR0 is set).
2. The firmware sends a packet containing less than the maximum packet size for Endpoint 0.
3. The firmware sends an empty data packet.

Until the transaction is terminated, the firmware simply needs to load the FIFO when it receives an interrupt which indicates that a packet has been sent from the FIFO. An interrupt is generated when TXPKTRDY is cleared.

When the firmware forces the termination of a transfer (by sending a short or empty data packet), it should set the DATAEND bit of PERI\_CSR0 (bit 3) to indicate to the core that the data phase is complete and that the core should next receive an acknowledge packet.

**Figure 16-6. Flow Chart of Transmit Data Stage of a Control Transfer in Peripheral Mode**

**16.3.8.1.1.4.4 Rx Mode: Control Transfer of Peripheral Mode**

In RX mode, all arriving data should be treated as part of a data phase until the expected amount of data has been received. If either a SETUP or an IN token is received while the endpoint is in RX state, a SETUPEND condition will occur as the controller expects only OUT tokens.

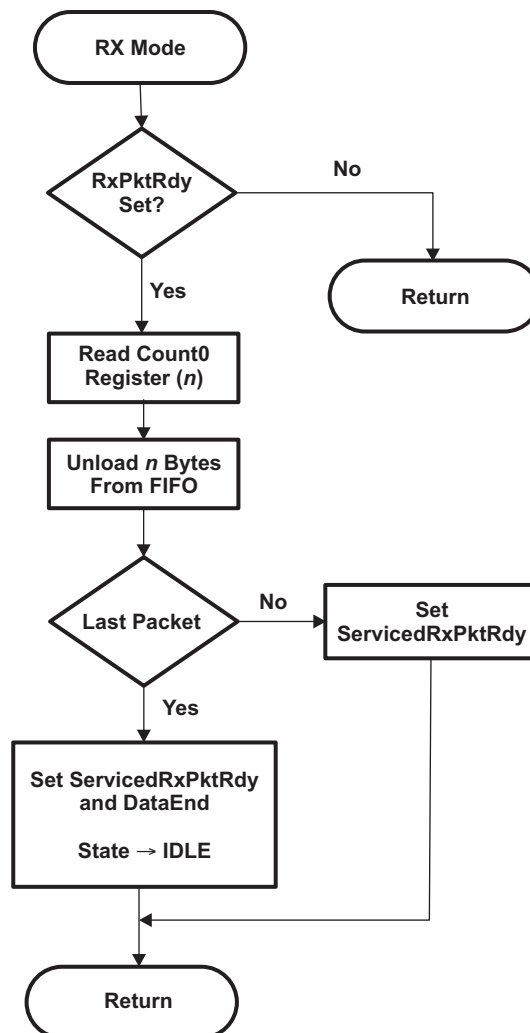

Three events can cause RX mode to be terminated before the expected amount of data has been received as shown in Figure 16-7:

1. The host sends an invalid token causing a SETUPEND condition (setting bit 4 of PERI\_CSR0).
2. The host sends a packet which contains less than the maximum packet size for endpoint 0.
3. The host sends an empty data packet.

Until the transaction is terminated, the software unloads the FIFO when it receives an interrupt that indicates new data has arrived (setting RXPkTRDY bit of PERI\_CSR0) and to clear RXPkTRDY by setting the SERV\_RXPKTRDY bit of PERI\_CSR0 (bit 6).

When the software detects the termination of a transfer (by receiving either the expected amount of data or an empty data packet), it should set the DATAEND bit (bit 3 of PERI\_CSR0) to indicate to the controller that the data phase is complete and that the core should receive an acknowledge packet next.

**Figure 16-7. Flow Chart of Receive Data Stage of a Control Transfer in Peripheral Mode**

#### 16.3.8.1.1.4.5 Error Handling: Control Transfer of Peripheral Mode

A control transfer may be aborted due to a protocol error on the USB, the host prematurely ending the transfer, or if the software wishes to abort the transfer (for example, because it cannot process the command).

The controller automatically detects protocol errors and sends a STALL packet to the host under the following conditions:

- The host sends more data during the OUT Data phase of a write request than was specified in the command. This condition is detected when the host sends an OUT token after the DATAEND bit (bit 3 of PERI\_CSR0) has been set.
- The host requests more data during the IN Data phase of a read request than was specified in the command. This condition is detected when the host sends an IN token after the DATAEND bit in the PERI\_CSR0 register has been set.
- The host sends more than Max Packet Size data bytes in an OUT data packet.
- The host sends a non-zero length DATA1 packet during the STATUS phase of a read request.

When the controller has sent the STALL packet, it sets the SENTSTALL bit (bit 2 of PERI\_CSR0) and generates an interrupt. When the software receives an endpoint 0 interrupt with the SENTSTALL bit set, it should abort the current transfer, clear the SENTSTALL bit, and return to the IDLE state.

If the host prematurely ends a transfer by entering the STATUS phase before all the data for the request has been transferred, or by sending a new SETUP packet before completing the current transfer, then the SETUPEND bit (bit 4 of PERI\_CSR0) will be set and an endpoint 0 interrupt generated. When the software receives an endpoint 0 interrupt with the SETUPEND bit set, it should abort the current transfer, set the SERV\_SETUPEND bit (bit 7 of PERI\_CSR0), and return to the IDLE state. If the RXPKTRDY bit (bit 0 of PERI\_CSR0) is set this indicates that the host has sent another SETUP packet and the software should then process this command.

If the software wants to abort the current transfer, because it cannot process the command or has some other internal error, then it should set the SENDSTALL bit (bit 5 of PERI\_CSR0). The controller will then send a STALL packet to the host, set the SENTSTALL bit (bit 2 of PERI\_CSR0) and generate an endpoint 0 interrupt.

#### 16.3.8.1.1.5 Additional Conditions: Control Transfer of Peripheral Mode

When working as a peripheral device, the controller automatically responds to certain conditions on the USB bus or actions by the host. The details are:

- Stall Issued to Control Transfers
  1. The host sends more data during an OUT Data phase of a Control transfer than was specified in the device request during the SETUP phase. This condition is detected by the controller when the host sends an OUT token (instead of an IN token) after the software has unloaded the last OUT packet and set DATAEND.
  2. The host requests more data during an IN data phase of a Control transfer than was specified in the device request during the SETUP phase. This condition is detected by the controller when the host sends an IN token (instead of an OUT token) after the software has cleared TXPKTRDY and set DATAEND in response to the ACK issued by the host to what should have been the last packet.
  3. The host sends more than MaxPktSize data with an OUT data token.
  4. The host sends the wrong PID for the OUT Status phase of a Control transfer.
  5. The host sends more than a zero length data packet for the OUT Status phase.
- Zero Length Out Data Packets In Control Transfer

A zero length OUT data packet is used to indicate the end of a Control transfer. In normal operation, such packets should only be received after the entire length of the device request has been transferred (i.e., after the software has set DataEnd). If, however, the host sends a zero length OUT data packet before the entire length of device request has been transferred, this signals the premature end of the transfer. In this case, the controller will automatically flush any IN token loaded by software ready for the Data phase from the FIFO and set SETUPEND bit (bit 4 of PERI\_CSR0).

### 16.3.8.1.2 Bulk Transfer: Peripheral Mode

Bulk transactions are handled by endpoints other than endpoint 0. It is used to handle non-periodic, large bursty communication typically used for a transfer that use any available bandwidth and can also be delayed until bandwidth is available.

#### 16.3.8.1.2.1 Bulk IN Transactions: Peripheral Mode

A Bulk IN transaction is used to transfer non-periodic data from the USB peripheral device to the host.

The following optional features are available for use with a Tx endpoint used in peripheral mode for Bulk IN transactions:

- **Double packet buffering:** When enabled, up to two packets can be stored in the FIFO awaiting transmission to the host. Double packet buffering is enabled by setting the DPB bit of TXFIFOSZ register (bit 4).
- **DMA:** If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint is able to accept another packet in its FIFO. This feature allows the DMA controller to load packets into the FIFO without processor intervention

##### 16.3.8.1.2.1.1 Bulk IN Transaction Setup: Peripheral Mode

In configuring a TX endpoint for bulk transactions, the TXMAXP register must be written with the maximum packet size (in bytes) for the endpoint. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the endpoint and the PERI\_TXCSR register (DMAEN and DMAMODE bit fields should be set when using DMA. [Table 16-4](#) displays the PERI\_TXCSR setting when used for Bulk transfer.

**Table 16-4. PERI\_TXCSR Register Bit Configuration for Bulk IN Transactions**

Bit Field	Bit Name	Description
Bit 15	AUTOSET	Cleared to 0 if using DMA. For CPU Mode use, if AUTOSET bit is set, the TXPKTRDY bit will be automatically set when data of the maximum packet size is loaded into the FIFO.
Bit 14	ISO	Cleared to 0 for bulk mode operation.
Bit 13	MODE	Set to 1 to make sure the FIFO is enabled (only necessary if the FIFO is shared with an RX endpoint)
Bit 12	DMAEN	Set to 1 to enable DMA usage; not needed if CPU is being used to service the Tx Endpoint
Bit 11	FRCDATATOG	Cleared to 0 to allow normal data toggle operations.
Bit 10	DMAMODE	Set to 1 when DMA is used to service Tx FIFO.

When the endpoint is first configured (following a SET\_CONFIGURATION or SET\_INTERFACE command on Endpoint 0), the lower byte of PERI\_TXCSR should be written to set the CLRDATATOG bit (bit 6). This will ensure that the data toggle (which is handled automatically by the controller) starts in the correct state.

Also if there are any data packets in the FIFO, indicated by the FIFONOTEMPTY bit (bit 1 of PERI\_TXCSR) being set, they should be flushed by setting the FLUSHFIFO bit (bit 3 of PERI\_TXCSR).

**NOTE:** It may be necessary to set this bit twice in succession if double buffering is enabled.

### 16.3.8.1.2.1.2 Bulk IN Operation: Peripheral Mode

When data is to be transferred over a Bulk IN pipe, a data packet needs to be loaded into the FIFO and the PERI\_TXCSR register written to set the TXPKTRDY bit (bit 0). When the packet has been sent, the TXPKTRDY bit will be cleared by the USB controller and an interrupt generated to signify to the user/application that the next packet can be loaded into the FIFO. If double packet buffering is enabled, then after the first packet has been loaded and the TXPKTRDY bit set, the TXPKTRDY bit will immediately be cleared (will not wait for the loaded first packet to be driven out) by the USB controller and an interrupt generated so that a second packet can be loaded into the FIFO. The software should operate in the same way, loading a packet when it receives an interrupt, regardless of whether double packet buffering is enabled or not.

In the general case, the packet size must not exceed the size specified by the lower 11 bits of the TXMAXP register. This part of the register defines the payload (packet size) for transfers over the USB and is required by the USB Specification to be either 8, 16, 32, 64 (Full-Speed or High-Speed) or 512 bytes (High-Speed only).

The host may determine that all the data for a transfer has been sent by knowing the total amount of data that is expected. Alternatively it may infer that all the data has been sent when it receives a packet which is smaller than the maximum packet size configuration for that particular endpoint (TXMAXP[10-0]). In the latter case, if the total size of the data block is a multiple of this payload, it will be necessary for the function to send a null packet after all the data has been sent. This is done by setting TXPKTRDY when the next interrupt is received, without loading any data into the FIFO.

If large blocks of data are being transferred, then the overhead of calling an interrupt service routine to load each packet can be avoided by using the CPPI DMA. A separate section detailing the use of the DMA is discussed within a latter section. Suffix is to say that the PERI\_TXCSR (DMAEN and DMAMODE) bit fields need to be set and the PERI\_TXCSR[AUTASET] bit cleared at the core level when using the DMA with an endpoint configured for any IN transaction/transfer.

### 16.3.8.1.2.1.3 Error Handling of Bulk IN Transfer: Peripheral Mode

If the software wants to shut down the Bulk IN pipe, it should set the SENDSTALL bit (bit 4 of PERI\_TXCSR). When the controller receives the next IN token, it will send a STALL to the host, set the SENTSTALL bit (bit 5 of PERI\_TXCSR) and generate an interrupt.

When the software receives an interrupt with the SENTSTALL bit (bit 5 of PERI\_TXCSR) set, it should clear the SENTSTALL bit. It should however leave the SENDSTALL bit set until it is ready to re-enable the Bulk IN pipe.

**NOTE:** If the host failed to receive the STALL packet for some reason, it will send another IN token, so it is advisable to leave the SENDSTALL bit set until the software is ready to re-enable the Bulk IN pipe. When a pipe is re-enabled, the data toggle sequence should be restarted by setting the CLRDATATOG bit in the PERI\_TXCSR register (bit 6).

### 16.3.8.1.2.2 Bulk OUT Transfer: Peripheral Mode

A Bulk OUT transaction is used to transfer non-periodic data from the host to the function controller.

The following optional features are available for use with an Rx endpoint used in peripheral mode for Bulk OUT transactions:

- Double packet buffering: When enabled, up to two packets can be stored in the FIFO on reception from the host. Double packet buffering is enabled by setting the DPB bit of the RXFIFOSZ register (bit 4).
- DMA: If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint has a packet in its FIFO. This feature can be used to allow the DMA controller to unload packets from the FIFO without processor intervention.

**NOTE:** When DMA is enabled, endpoint interrupt will not be generated for completion of packet reception. Endpoint interrupt will be generated only in the error conditions.

### 16.3.8.1.2.2.1 Bulk OUT Transfer Setup: Peripheral Mode

In configuring an Rx endpoint for Bulk OUT transactions, the RXMAXP register must be written with the maximum packet size (in bytes) for the endpoint. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the endpoint. When using DMA for Rx Endpoints, the PERI\_RXCSR needs to have its DMAEN bit set and have its AUTOCLEAR and DMAMODE bits cleared. In addition, the relevant interrupt enable bit in the INTRRXE register should be set (if an interrupt is required for this endpoint) and the PERI\_RXCSR register should be set as shown in [Table 16-5](#).

**Table 16-5. PERI\_RXCSR Register Bit Configuration for Bulk OUT Transactions**

Bit Field	Bit Name	Description
Bit 15	AUTOCLEAR	Cleared to 0 if using DMA. In CPU Mode of usage, if the CPU sets AUTOCLEAR bit, the RXPKTRDY bit will be automatically cleared when a packet of RXMAXP bytes has been unloaded from the Receive FIFO.
Bit 14	ISO	Cleared to 0 to enable Bulk protocol.
Bit 13	DMAEN	Set to 1 if a DMA request is required for this Rx endpoint.
Bit 12	DISNYET	Cleared to 0 to allow normal PING flow control. This will affect only high speed transactions.
Bit 11	DMAMODE	Always clear this bit to 0.

When the Rx endpoint is first configured (following a SET\_CONFIGURATION or SET\_INTERFACE command on Endpoint 0), the lower byte of PERI\_RXCSR should be written to set the CLRDATATOG bit (bit 7). This will ensure that the data toggle (which is handled automatically by the USB controller) starts in the correct state.

Also if there are any data packets in the FIFO (indicated by the RXPKTRDY bit (bit 0 of PERI\_RXCSR) being set), they should be flushed by setting the FLUSHFIFO bit (bit 4 of PERI\_RXCSR).

**NOTE:** It may be necessary to set this bit twice in succession if double buffering is enabled.

### 16.3.8.1.2.2.2 Bulk OUT Operation: Peripheral Mode

When a data packet is received by a Bulk Rx endpoint, the RXPKTRDY bit (bit 0 of PERI\_RXCSR) is set and an interrupt is generated. The software should read the RXCOUNT register for the endpoint to determine the size of the data packet. The data packet should be read from the FIFO, and then the RXPKTRDY bit should be cleared.

The packets received should not exceed the size specified in the RXMAXP register (as this should be the value set in the wMaxPacketSize field of the endpoint descriptor sent to the host). When a block of data larger than wMaxPacketSize needs to be sent to the function, it will be sent as multiple packets. All the packets will be wMaxPacketSize in size, except the last packet which will contain the residue. The software may use an application specific method of determining the total size of the block and hence when the last packet has been received. Alternatively it may infer that the entire block has been received when it receives a packet which is less than wMaxPacketSize in size. (If the total size of the data block is a multiple of wMaxPacketSize, a null data packet will be sent after the data to signify that the transfer is complete.)

In the general case, the application software will need to read each packet from the FIFO individually. If large blocks of data are being transferred, the overhead of calling an interrupt service routine to unload each packet can be avoided by using DMA.

### 16.3.8.1.2.2.3 Bulk OUT Error Handling: Peripheral Mode

If the software wants to shut down the Bulk OUT pipe, it should set the SENDSTALL bit (bit 5 of PERI\_RXCSR). When the controller receives the next packet it will send a STALL to the host, set the SENTSTALL bit (bit 6 of PERI\_RXCSR) and generate an interrupt.

When the software receives an interrupt with the SENTSTALL bit (bit 6 of PERI\_RXCSR) set, it should clear this bit. It should however leave the SENDSTALL bit set until it is ready to re-enable the Bulk OUT pipe.

**NOTE:** If the host failed to receive the STALL packet for some reason, it will send another packet, so it is advisable to leave the SENDSTALL bit set until the software is ready to re-enable the Bulk OUT pipe. When a Bulk OUT pipe is re-enabled, the data toggle sequence should be restarted by setting the CLRDATATOG bit (bit 7) in the PERI\_RXCSR register.

### 16.3.8.1.3 Interrupt Transfer: Peripheral Mode

An Interrupt IN transaction uses the same protocol as a Bulk IN transaction and the configuration and operation mentioned on prior sections apply to Interrupt transfer too with minor changes. Similarly, an Interrupt OUT transaction uses almost the same protocol as a Bulk OUT transaction and can be used the same way.

Tx endpoints in the USB controller have one feature for Interrupt IN transactions that they do not support in Bulk IN transactions. In Interrupt IN transactions, the endpoints support continuous toggle of the data toggle bit.

This feature is enabled by setting the FRCDATATOG bit in the PERI\_TXCSR register (bit 11). When this bit is set, the controller will consider the packet as having been successfully sent and toggle the data bit for the endpoint, regardless of whether an ACK was received from the host.

Another difference is that interrupt endpoints do not support PING flow control. This means that the controller should never respond with a NYET handshake, only ACK/NAK/STALL. To ensure this, the DISNYET bit in the PERI\_RXCSR register (bit 12) should be set to disable the transmission of NYET handshakes in high-speed mode.

Though DMA can be used with an interrupt OUT endpoint, it generally offers little benefit as interrupt endpoints are usually expected to transfer all their data in a single packet.

### 16.3.8.1.4 Isochronous Transfer: Peripheral Mode

Isochronous transfers are used when working with isochronous data. Isochronous transfers provide periodic, continuous communication between host and device.

#### 16.3.8.1.4.1 Isochronous IN Transactions: Peripheral Mode

An Isochronous IN transaction is used to transfer periodic data from the function controller to the host.

The following optional features are available for use with a Tx endpoint used in Peripheral mode for Isochronous IN transactions:

- Double packet buffering: When enabled, up to two packets can be stored in the FIFO awaiting transmission to the host. Double packet buffering is enabled by setting the DPB bit of TXFIFOSZ register (bit 4).

**NOTE:** Double packet buffering is generally advisable for isochronous transactions in order to avoid underrun errors as described in later section.

- DMA: If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint is able to accept another packet in its FIFO. This feature allows the DMA controller to load packets into the FIFO without processor intervention.

However, this feature is not particularly useful with Isochronous endpoints because the packets transferred are often not maximum packet size and the PERI\_TXCSR register needs to be accessed following every packet to check for Underrun errors.

When DMA is enabled and DMAMODE bit of PERI\_TXCSR is set, endpoint interrupt will not be generated for completion of packet transfer. Endpoint interrupt will be generated only in the error conditions.

#### 16.3.8.1.4.1.1 Isochronous IN Transfer Setup: Peripheral Mode

In configuring a Tx endpoint for Isochronous IN transactions, the TXMAXP register must be written with the maximum packet size (in bytes) for the endpoint. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the endpoint. In addition, the relevant interrupt enable bit in the INTRTXE register should be set (if an interrupt is required for this endpoint) and the PERI\_TXCSR register should be set as shown in [Table 16-6](#).

**Table 16-6. PERI\_TXCSR Register Bit Configuration for Isochronous IN Transactions**

Bit Field	Bit Name	Description
Bit 14	ISO	Set to 1 to enable Isochronous transfer protocol.
Bit 13	MODE	Set to 1 to ensure the FIFO is enabled (only necessary if the FIFO is shared with an Rx endpoint).
Bit 12	DMAEN	Set to 1 if DMA Requests have to be enabled.
Bit 11	FRCDATATOG	Ignored in Isochronous mode.
Bit 10	DMAMODE	Set to 1 when DMA is enabled.

#### 16.3.8.1.4.1.2 Isochronous IN Transfer Operation: Peripheral Mode

An isochronous endpoint does not support data retries, so if data underrun is to be avoided, the data to be sent to the host must be loaded into the FIFO before the IN token is received. The host will send one IN token per frame (or microframe in High-speed mode), however the timing within the frame (or microframe) can vary. If an IN token is received near the end of one frame and then at the start of the next frame, there will be little time to reload the FIFO. For this reason, double buffering of the endpoint is usually necessary.

An interrupt is generated whenever a packet is sent to the host and the software may use this interrupt to load the next packet into the FIFO and set the TXPKTRDY bit in the PERI\_TXCSR register (bit 0) in the same way as for a Bulk Tx endpoint. As the interrupt could occur almost any time within a frame(/microframe), depending on when the host has scheduled the transaction, this may result in irregular timing of FIFO load requests. If the data source for the endpoint is coming from some external hardware, it may be more convenient to wait until the end of each frame(/microframe) before loading the FIFO as this will minimize the requirement for additional buffering. This can be done by using either the SOF interrupt or the external SOF\_PULSE signal from the controller to trigger the loading of the next data packet. The SOF\_PULSE is generated once per frame(/microframe) when a SOF packet is received. (The controller also maintains an external frame(/microframe) counter so it can still generate a SOF\_PULSE when the SOF packet has been lost.) The interrupts may still be used to set the TXPKTRDY bit in PERI\_TXCSR (bit 0) and to check for data overruns/underruns.

Starting up a double-buffered Isochronous IN pipe can be a source of problems. Double buffering requires that a data packet is not transmitted until the frame(/microframe) after it is loaded. There is no problem if the function loads the first data packet at least a frame(/microframe) before the host sets up the pipe (and therefore starts sending IN tokens). But if the host has already started sending IN tokens by the time the first packet is loaded, the packet may be transmitted in the same frame(/microframe) as it is loaded, depending on whether it is loaded before, or after, the IN token is received. This potential problem can be avoided by setting the ISOUPDATE bit in the POWER register (bit 7). When this bit is set, any data packet loaded into an Isochronous Tx endpoint FIFO will not be transmitted until after the next SOF packet has been received, thereby ensuring that the data packet is not sent too early.

#### 16.3.8.1.4.1.3 Isochronous IN Error Handling: Peripheral Mode

If the endpoint has no data in its FIFO when an IN token is received, it will send a null data packet to the host and set the UNDERRUN bit in the PERI\_TXCSR register (bit 2). This is an indication that the software is not supplying data fast enough for the host. It is up to the application to determine how this error condition is handled.

If the software is loading one packet per frame(/microframe) and it finds that the TXPKTRDY bit in the PERI\_TXCSR register (bit 0) is set when it wants to load the next packet, this indicates that a data packet has not been sent (perhaps because an IN token from the host was corrupted). It is up to the application how it handles this condition: it may choose to flush the unsent packet by setting the FLUSHFIFO bit in the PERI\_TXCSR register (bit 3), or it may choose to skip the current packet.

#### 16.3.8.1.4.2 Isochronous OUT Transactions: Peripheral Mode

An isochronous OUT transaction is used to transfer periodic data from the host to the function controller.

Following optional features are available for use with an Rx endpoint used in Peripheral mode for Isochronous OUT transactions:

- **Double packet buffering:** When enabled, up to two packets can be stored in the FIFO on reception from the host. Double packet buffering is enabled by setting the DPB bit of RXFIFOSZ register (bit 4).  
**NOTE:** Double packet buffering is generally advisable for Isochronous transactions in order to avoid overrun errors.
- **DMA:** If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint has a packet in its FIFO. This feature can be used to allow the DMA controller to unload packets from the FIFO without processor intervention.

However, this feature is not particularly useful with Isochronous endpoints because the packets transferred are often not maximum packet size and the PERI\_RXCSR register needs to be accessed following every packet to check for Overrun or CRC errors.

When DMA is enabled, endpoint interrupt will not be generated for completion of packet reception. Endpoint interrupt will be generated only in the error conditions.

##### 16.3.8.1.4.2.1 Isochronous OUT Setup: Peripheral Mode

In configuring an Rx endpoint for Isochronous OUT transactions, the RXMAXP register must be written with the maximum packet size (in bytes) for the endpoint. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the endpoint. In addition, the relevant interrupt enable bit in the INTRRXE register should be set (if an interrupt is required for this endpoint) and the PERI\_RXCSR register should be set as shown in [Table 16-7](#).

**Table 16-7. PERI\_RXCSR Register Bit Configuration for Isochronous OUT Transactions**

Bit Field	Bit Name	Description
Bit 15	AUTOCLEAR	Cleared to 0 if using DMA. In CPU Mode of usage, if the CPU sets AUTOCLEAR bit, the RXPKTRDY bit will be automatically cleared when a packet of RXMAXP bytes has been unloaded from the Receive FIFO.
Bit 14	ISO	Set to 1 to configure endpoint usage for Isochronous transfer.
Bit 13	DMAEN	Set to 1 if a DMA request is required for this Rx endpoint.
Bit 12	DISNYET	Ignored in Isochronous Mode.
Bit 11	DMAMODE	Always clear this bit to 0.

### 16.3.8.1.4.2.2 Isochronous OUT Operation: Peripheral Mode

An Isochronous endpoint does not support data retries so, if a data overrun is to be avoided, there must be space in the FIFO to accept a packet when it is received. The host will send one packet per frame (or microframe in High-speed mode); however, the time within the frame can vary. If a packet is received near the end of one frame(/microframe) and another arrives at the start of the next frame, there will be little time to unload the FIFO. For this reason, double buffering of the endpoint is usually necessary.

An interrupt is generated whenever a packet is received from the host and the software may use this interrupt to unload the packet from the FIFO and clear the RXPKTRDY bit in the PERI\_RXCSR register (bit 0) in the same way as for a Bulk Rx endpoint. As the interrupt could occur almost any time within a frame(/microframe), depending on when the host has scheduled the transaction, the timing of FIFO unload requests will probably be irregular. If the data sink for the endpoint is going to some external hardware, it may be better to minimize the requirement for additional buffering by waiting until the end of each frame(/microframe) before unloading the FIFO. This can be done by using either the SOF interrupt or the external SOF\_PULSE signal from the controller to trigger the unloading of the data packet. The SOF\_PULSE is generated once per frame(/microframe) when a SOF packet is received. (The controller also maintains an external frame(/microframe) counter so it can still generate a SOF\_PULSE when the SOF packet has been lost.) The interrupts may still be used to clear the RXPKTRDY bit in PERI\_RXCSR and to check for data overruns/underruns.

### 16.3.8.1.4.2.3 Isochronous OUT Error Handling: Peripheral Mode

If there is no space in the FIFO to store a packet when it is received from the host, the OVERRUN bit in the PERI\_RXCSR register (bit 2) will be set. This is an indication that the software is not unloading data fast enough for the host. It is up to the application to determine how this error condition is handled

If the controller finds that a received packet has a CRC error, it will still store the packet in the FIFO and set the RXPKTRDY bit (bit 0 of PERI\_RXCSR) and the DATAERROR bit (bit 3 of PERI\_RXCSR). It is left up to the application to determine how this error condition is handled.

The number of USB packets sent in any microframe will depend on the amount of data to be transferred, and is indicated through the PIDs used for the individual packets. If the indicated number of packets have not been received by the end of a microframe, the INCOMPRX bit (bit 8) bit in the PERI\_RXCSR register will be set to indicate that the data in the FIFO is incomplete. Equally, if a packet of the wrong data type is received, then the PID Error bit in the PERI\_RXCSR register will be set. In each case, an interrupt will, however, still be generated to allow the data that has been received to be read from the FIFO.

**Note:** The circumstances in which a PID Error or INCOMPRX is reported depends on the precise sequence of packets received.

When the core is operating in peripheral mode, the details are in [Table 16-8](#).

**Table 16-8. Isochronous OUT Error Handling: Peripheral Mode**

No. Packet(s) Expected	Data Packet(s) Received	Response
1	DATA0	OK
	DATA1	PID Error set
	DATA2	PID Error set
	MDATA	PID Error set
2	DATA0	OK
	DATA1	INCOMPRX Set
	DATA2	INCOMPRX Set + PID Error set
	MDATA	INCOMPRX Set
	MDATA DATA0	PID Error Set
	MDATA DATA1	OK
	MDATA DATA2	PID Error Set
3	MDATA MDATA	PID Error Set
	DATA0	OK
	DATA1	INCOMPRX Set

**Table 16-8. Isochronous OUT Error Handling: Peripheral Mode (continued)**

No. Packet(s) Expected	Data Packet(s) Received	Response
	DATA2	INCOMPRX Set
	MDATA	INCOMPRX Set
	MDATA DATA0	PID Error set
	MDATA DATA1	OK
	MDATA DATA2	INCOMPRX Set
	MDATA MDATA	INCOMPRX Set
	MDATA MDATA DATA0	PID Error set
	MDATA MDATA DATA1	PID Error set
	MDATA MDATA DATA2	OK
	MDATA MDATA MDATA	PID Error set

### 16.3.8.2 USB Controller Host Mode Operation

The USB controller assumes the role of a host when the USBx\_ID pin state is grounded or USB Mode Register[iddig=bit8] is cleared to 0 (provided that iddig\_mux, which is bit7 of USBnMODE is also set to 1) by the user application prior to the controller goes into session. When the USB controller go into session, application/firmware sets the DEVCTL[SESSION] bit to 1, it will assume the role of a host.

- **Entry into Suspend mode.** When operating as a host, the USB controller can be prompted to go into Suspend mode by setting the SUSPENDM bit in the POWER register. When this bit is set, the controller will complete the current transaction then stop the transaction scheduler and frame counter. No further transactions will be started and no SOF packets will be generated. If the ENSUSPM bit (bit 0 of POWER register) is set, the UTMI+ PHY will go into low-power mode when the controller goes into suspend mode.
- **Sending Resume Signaling.** When the application requires the controller to leave suspend mode, it needs to clear the SUSPENDM bit in the POWER register, set the RESUME bit and leave it set for 20ms. While the RESUME bit is high, the controller will generate Resume signaling on the bus. After 20 ms, the CPU should clear the RESUME bit, at which point the frame counter and transaction scheduler will be started.
- **Responding to Remote Wake-up.** If Resume signaling is detected from the target while the controller is in suspend mode, the UTMI+ PHY will be brought out of low-power mode and UTMI clock is restarted. The controller will then exit suspend mode and automatically set the RESUME bit in the POWER register (bit 2) to '1' to take over generating the Resume signaling from the target. If the resume interrupt is enabled, an interrupt will be generated.
- **Reset Signaling.** If the RESET bit in the POWER register (bit 3) is set while the controller is in Host mode, it will generate Reset signaling on the bus. If the HSENAB bit in the POWER register (bit 5) was set, it will also try to negotiate for high-speed operation. The software should keep the RESET bit set for at least 20 ms to ensure correct resetting of the target device. After the software has cleared the bit, the controller will start its frame counter and transaction scheduler. Whether high-speed operation is selected will be indicated by HSMODE bit of POWER register (bit 4).

### 16.3.8.2.1 Control Transactions: Host Mode

Host control transactions are conducted through Endpoint 0 and the software is required to handle all the Standard Device Requests that may be sent or received via Endpoint 0 (as described in Universal Serial Bus Specification, Revision 2.0). Endpoint 0 can only be serviced via CPU and DMA mode can not be used.

There are three categories of Standard Device Requests to be handled: Zero Data Requests (in which all the information is included in the command); Write Requests (in which the command will be followed by additional data); and Read Requests (in which the device is required to send data back to the host).

1. Zero Data Requests comprise a SETUP command followed by an IN Status Phase.
2. Write Requests comprise a SETUP command, followed by an OUT Data Phase which is in turn followed by an IN Status Phase.
3. Read Requests comprise a SETUP command, followed by an IN Data Phase which is in turn followed by an OUT Status Phase.

A timeout may be set to limit the length of time for which the host controller will retry a transaction which is continually NAKed by the target. This limit can be between 2 and 2 15 frames/microframes and is set through the NAKLIMIT0 register.

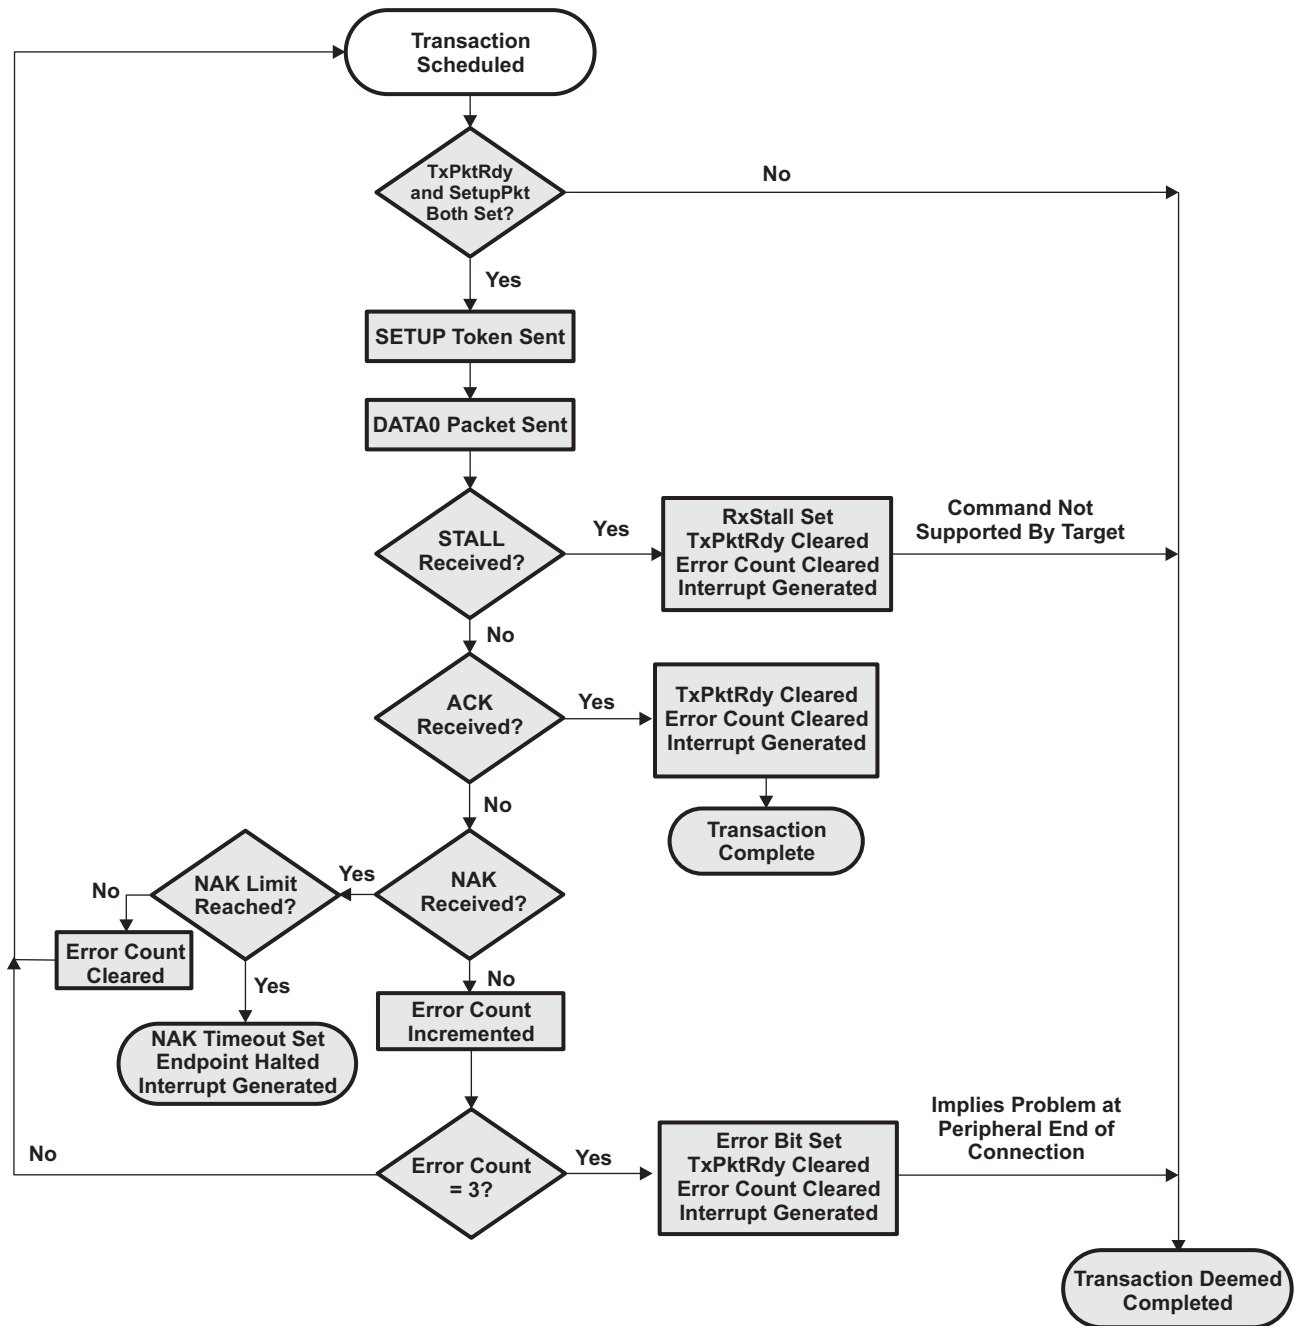

The following sections describe the actions that the CPU needs to take in issuing these different types of request through looking at the steps to take in the different phases of a control transaction.

Note: Before initiating any transactions as a Host, the FADDR register needs to be set to address the peripheral device. When the device is first connected, FADDR should be set to zero. After a SET\_ADDRESS command is issued, FADDR should be set the target's new address.

#### 16.3.8.2.1.1 Setup Phase of Control Transaction: Host Mode

For the SETUP Phase of a control transaction ([Figure 16-8](#)), the software driving the USB host device needs to:

1. Load the 8 bytes of the required Device request command into the Endpoint 0 FIFO
2. Set SETUPPKT and TXPKTRDY (bits 3 and 1 of HOST\_CSR0, respectively).  
**NOTE:** These bits must be set together.  
 The controller then proceeds to send a SETUP token followed by the 8-byte command/request to Endpoint 0 of the addressed device, retrying as necessary. *Note:* On errors, the controller retries the transaction three times.
3. At the end of the attempt to send the 8-byte request data, the controller will generate an Endpoint 0 interrupt. The software should then read HOST\_CSR0 to establish whether the RXSTALL bit (bit 2), the ERROR bit (bit 4) or the NAK\_TIMEOUT bit (bit 7) has been set.  
 If RXSTALL is set, it indicates that the target did not accept the command (for example, because it is not supported by the target device) and so has issued a STALL response. If ERROR is set, it means that the controller has tried to send the SETUP Packet and the following data packet three times without getting any response.  
 If NAK\_TIMEOUT is set, it means that the controller has received a NAK response to each attempt to send the SETUP packet, for longer than the time set in HOST\_NAKLIMIT0. The controller can then be directed either to continue trying this transaction (until it times out again) by clearing the NAK\_TIMEOUT bit or to abort the transaction by flushing the FIFO before clearing the NAK\_TIMEOUT bit.
4. If none of RXSTALL, ERROR or NAK\_TIMEOUT is set, the SETUP Phase has been correctly ACKed and the software should proceed to the following IN Data Phase, OUT Data Phase or IN Status Phase specified for the particular Standard Device Request.

**Figure 16-8. Flow Chart of Setup Stage of a Control Transfer in Host Mode**

#### 16.3.8.2.1.2 Data Phase (IN Data Phase) of a Control Transaction: Host Mode

For the IN Data Phase of a control transaction (Figure 16-9), the software driving the USB host device needs to

1. Set REQPKT bit of HOST\_CSR0 (bit 5)
2. Wait while the controller sends the IN token and receives the required data back.
3. When the controller generates the Endpoint 0 interrupt, read HOST\_CSR0 to establish whether the RXSTALL bit (bit 2), the ERROR bit (bit 4), the NAK\_TIMEOUT bit (bit 7) or RXPKTTRDY bit (bit 0) has been set.  
If RXSTALL is set, it indicates that the target has issued a STALL response.

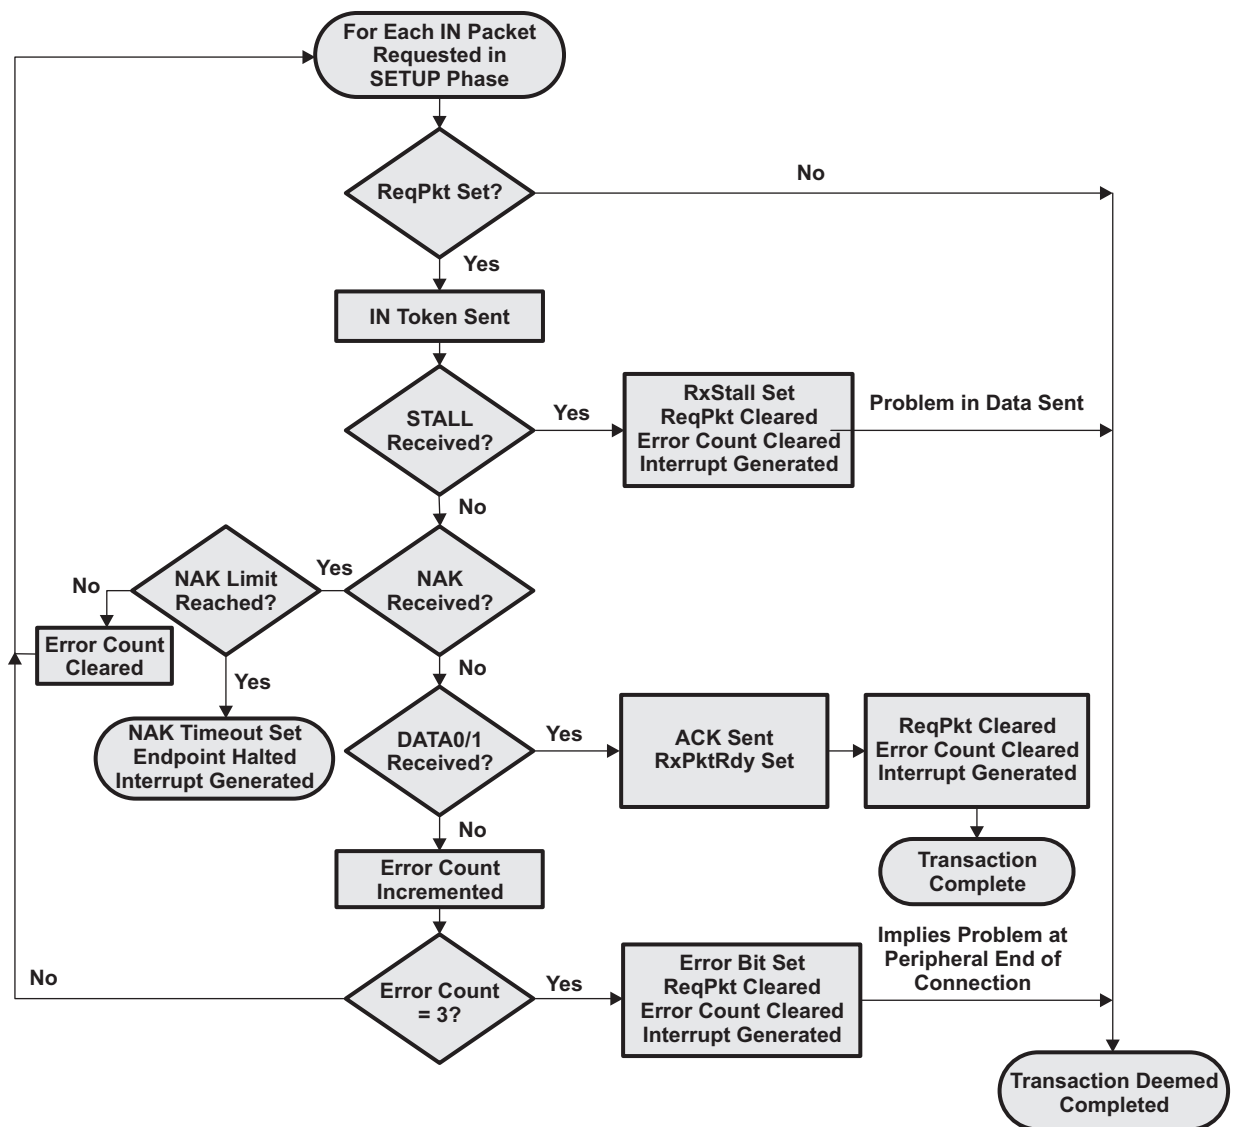

If ERROR is set, it means that the controller has tried to send the required IN token three times without getting any response. If NAK\_TIMEOUT bit is set, it means that the controller has received a NAK response to each attempt to send the IN token, for longer than the time set in HOST\_NAKLIMIT0. The controller can then be directed either to continue trying this transaction (until it times out again) by clearing the NAK\_TIMEOUT bit or to abort the transaction by clearing REQPKT before clearing the NAK\_TIMEOUT bit

4. If RXPKTTRDY has been set, the software should read the data from the Endpoint 0 FIFO, then clear RXPKTTRDY.
5. If further data is expected, the software should repeat Steps 1-4.

When all the data has been successfully received, the CPU should proceed to the OUT Status Phase of the Control Transaction.

**Figure 16-9. Flow Chart of Data Stage (IN Data Phase) of a Control Transfer in Host Mode**

### 16.3.8.2.1.3 Data Phase (OUT Data Phase) of a Control Transaction: Host Mode

For the OUT Data Phase of a control transaction (Figure 16-10), the software driving the USB host device needs to:

1. Load the data to be sent into the endpoint 0 FIFO.
2. Set the TXPKTRDY bit of HOST\_CSR0 (bit 1). The controller then proceeds to send an OUT token followed by the data from the FIFO to Endpoint 0 of the addressed device, retrying as necessary.
3. At the end of the attempt to send the data, the controller will generate an Endpoint 0 interrupt. The software should then read HOST\_CSR0 to establish whether the RXSTALL bit (bit 2), the ERROR bit (bit 4) or the NAK\_TIMEOUT bit (bit 7) has been set.
  - If RXSTALL bit is set, it indicates that the target has issued a STALL response.
  - If ERROR bit is set, it means that the controller has tried to send the OUT token and the following data packet three times without getting any response. If NAK\_TIMEOUT is set, it means that the controller has received a NAK response to each attempt to send the OUT token, for longer than the time set in the HOST\_NAKLIMIT0 register. The controller can then be directed either to continue trying this transaction (until it times out again) by clearing the NAK\_TIMEOUT bit or to abort the transaction by flushing the FIFO before clearing the NAK\_TIMEOUT bit.
  - If none of RXSTALL, ERROR or NAKLIMIT is set, the OUT data has been correctly ACKed.
4. If further data needs to be sent, the software should repeat Steps 1-3.  
When all the data has been successfully sent, the software should proceed to the IN Status Phase of the Control Transaction.

Figure 16-10. Flow Chart of Data Stage (OUT Data Phase) of a Control Transfer in Host Mode

16.3.8.2.1.4 Status Phase (Status for OUT Data Phase or Setup Phase) of a Control Transaction: Host Mode

IN Status Phase of a control transfer exists for a Zero Data Request or for a Write Request of a control transfer. The IN Status Phase follows the Setup Stage, if no Data Stage of a control transfer exists, or OUT Data Phase of a Data Stage of a control transfer.

For the IN Status Phase of a control transaction (Figure 16-11), the software driving the USB Host device needs to:

1. Set the STATUSPKT and REQPKT bits of HOST\_CSR0 (bit 6 and bit 5, respectively).
2. Wait while the controller sends an IN token and receives a response from the USB peripheral device.
3. When the controller generates the Endpoint 0 interrupt, read HOST\_CSR0 to establish whether the RXSTALL bit (bit 2), the ERROR bit (bit 4), the NAK\_TIMEOUT bit (bit 7) or RXPKTRDY bit (bit 0) has been set.

If RXSTALL bit is set, it indicates that the target could not complete the command and so has issued a

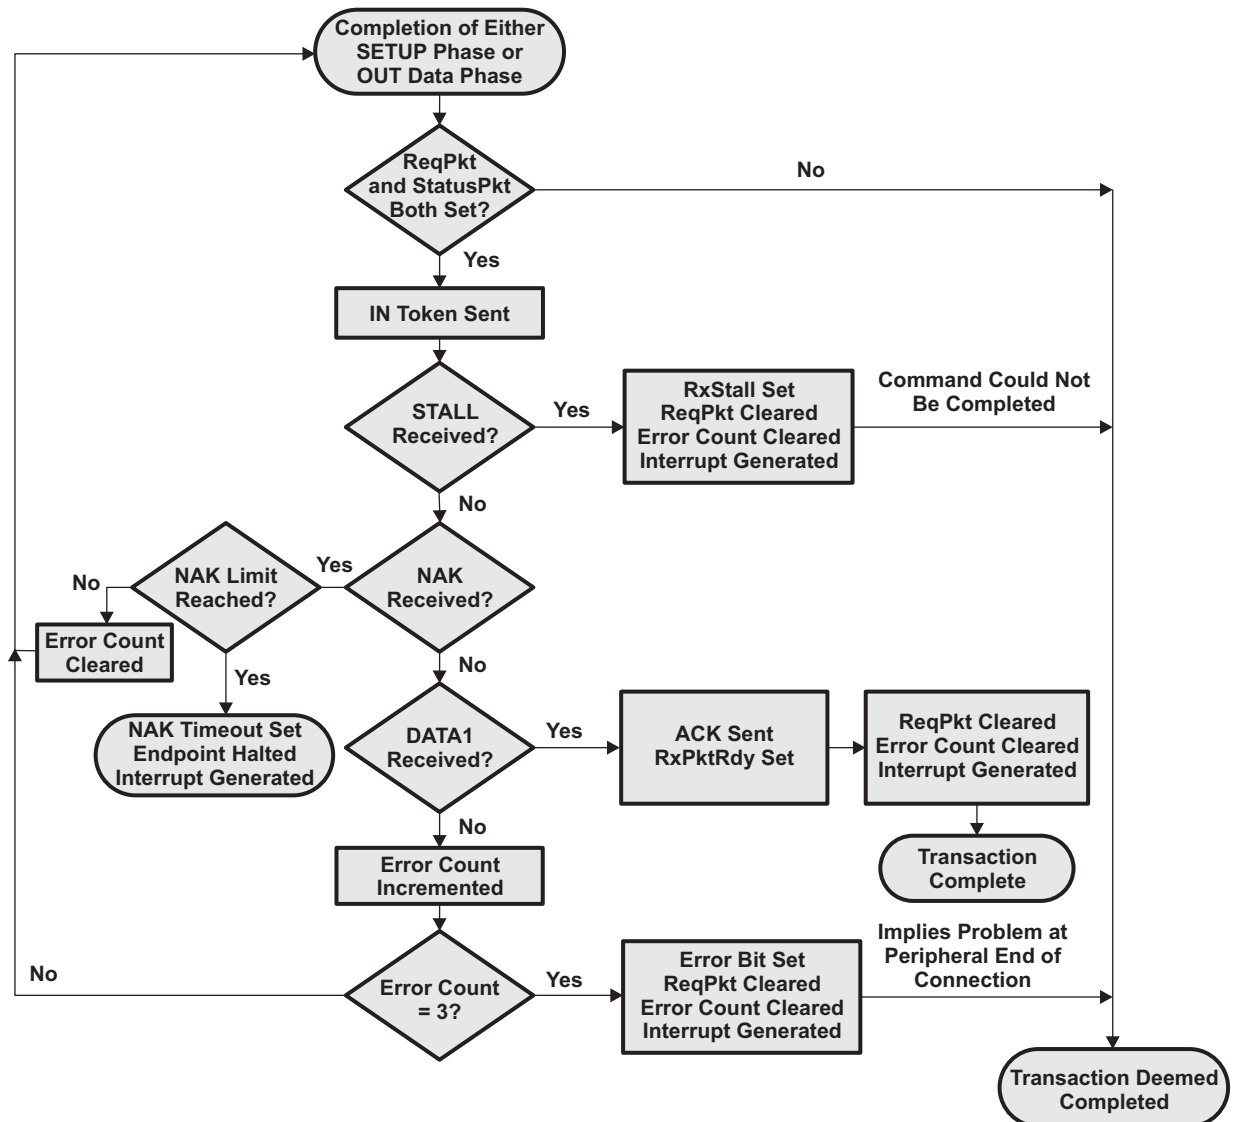

STALL response.

If ERROR bit is set, it means that the controller has tried to send the required IN token three times without getting any response.

If NAK\_TIMEOUT bit is set, it means that the controller has received a NAK response to each attempt to send the IN token, for longer than the time set in the HOST\_NAKLIMIT0 register. The controller can then be directed either to continue trying this transaction (until it times out again) by clearing the NAK\_TIMEOUT bit or to abort the transaction by clearing REQPKT bit and STATUSPKT bit before clearing the NAK\_TIMEOUT bit.

4. The CPU should clear the STATUSPPKT bit of HOST\_CSR0 together with (i.e., in the same write operation as) RxPktRdy if this has been set.

**Figure 16-11. Flow Chart of Status Stage of Zero Data Request or Write Request of a Control Transfer in Host Mode**

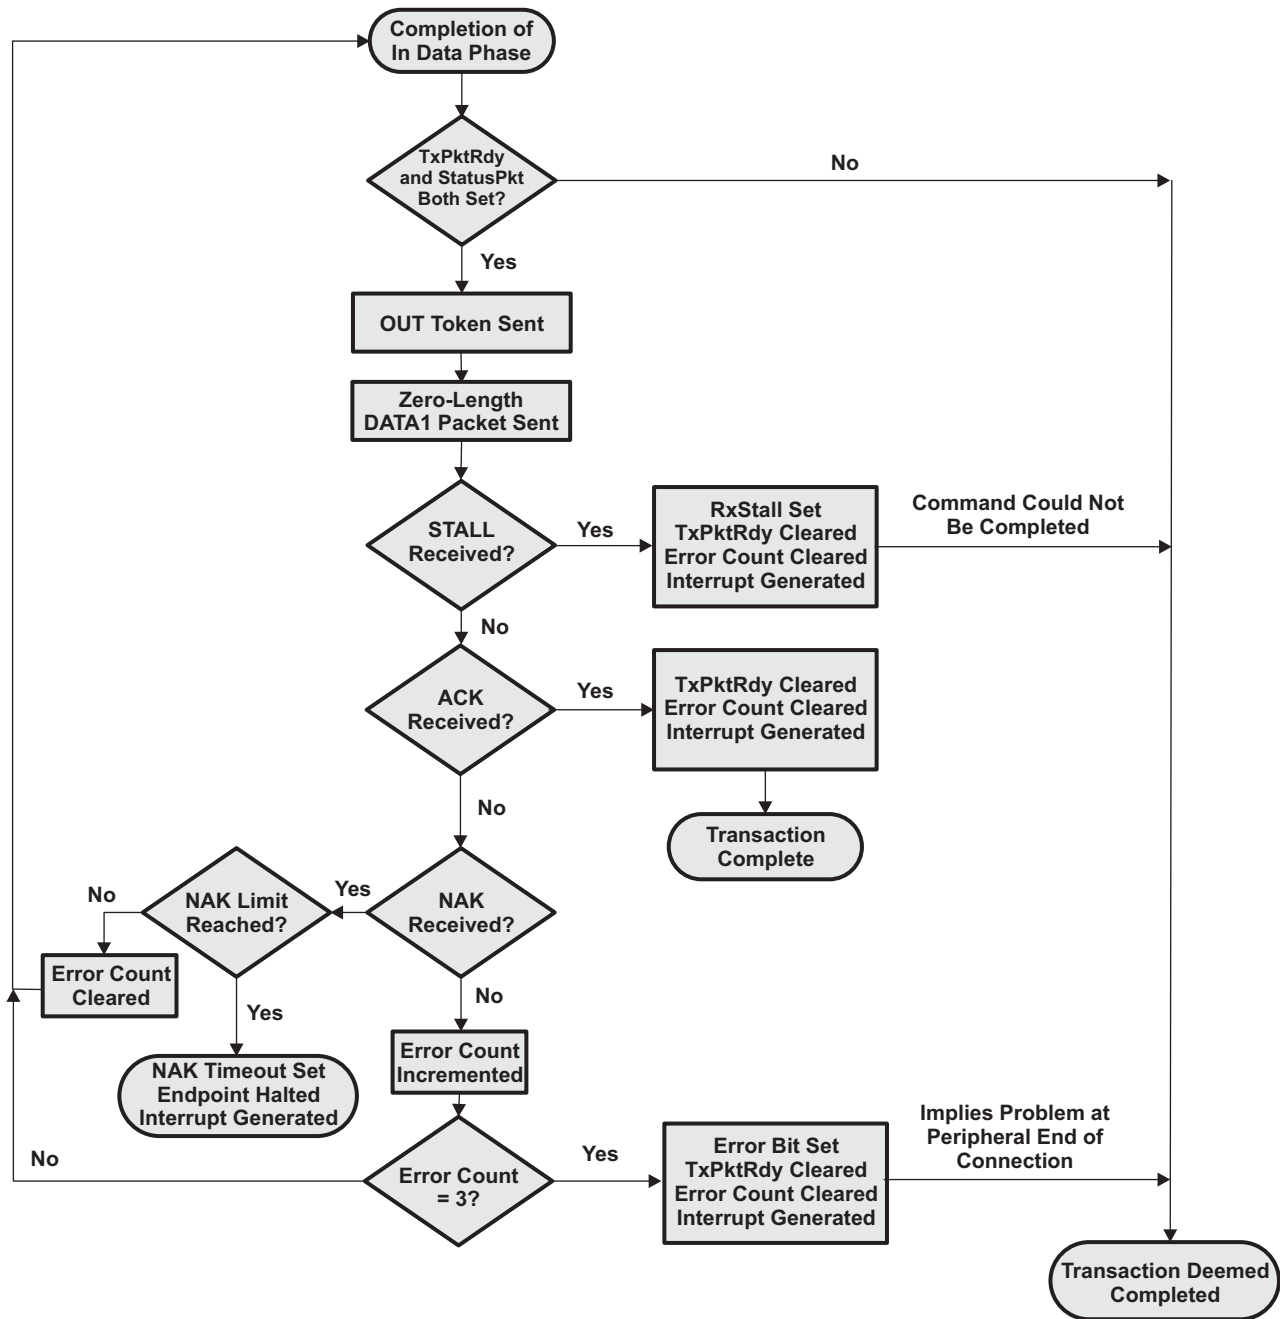

**16.3.8.2.1.5 Status Phase for a Read Request of a Control Transaction: Host Mode**

OUT Status Phase of a control transfer exist for a Read Request or a control transfer where data was received by the host controller. The OUT Status phase follows the IN Data Stage of a control transfer.

For the OUT Status Phase of a control transaction (Figure 16-12), the CPU driving the host device needs to:

1. Set STATUSPKT and TXPKTRDY bits of HOST\_CSR0 (bit 6 and bit 1, respectively).  
NOTE: These bits need to be set together
2. Wait while the controller sends the OUT token and a zero-length DATA1 packet.
3. At the end of the attempt to send the data, the controller will generate an Endpoint 0 interrupt. The software should then read HOST\_CSR0 to establish whether the RXSTALL bit (bit 2), the ERROR bit (bit 4) or the NAK\_TIMEOUT bit (bit 7) has been set.  
If RXSTALL bit is set, it indicates that the target could not complete the command and so has issued a STALL response.  
If ERROR bit is set, it means that the controller has tried to send the STATUS Packet and the following data packet three times without getting any response.  
If NAK\_TIMEOUT bit is set, it means that the controller has received a NAK response to each attempt to send the IN token, for longer than the time set in the HOST\_NAKLIMIT0 register. The controller can then be directed either to continue trying this transaction (until it times out again) by clearing the NAK\_TIMEOUT bit or to abort the transaction by flushing the FIFO before clearing the NAK\_TIMEOUT bit.
4. If none of RXSTALL, ERROR or NAK\_TIMEOUT bits is set, the STATUS Phase has been correctly ACKed.

Figure 16-12. Chart of Status Stage of a Read Request of a Control Transfer in Host Mode

### 16.3.8.2.2 Bulk Transfer: Host Mode

Bulk transactions are handled by endpoints other than endpoint 0. It is used to handle non-periodic, large bursty communication typically used for a transfer that use any available bandwidth and can also be delayed until bandwidth is available.

#### 16.3.8.2.2.1 Bulk IN Transactions: Host Mode

A Bulk IN transaction may be used to transfer non-periodic data from the external USB peripheral to the host.

The following optional features are available for use with an Rx endpoint used in host mode to receive the data:

- Double packet buffering: When enabled, up to two packets can be stored in the FIFO on reception from the host. This allows that one packet can be received while another is being read. Double packet buffering is enabled by setting the DPB bit of RXFIFOSZ register (bit 4).
- DMA: If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint has a packet in its FIFO. This feature can be used to allow the DMA controller to unload packets from the FIFO without processor intervention.  
When DMA is enabled, endpoint interrupt will not be generated for completion of packet reception. Endpoint interrupt will be generated only in the error conditions. For more information see section on CPPI DMA

#### 16.3.8.2.2.1.1 Bulk IN Setup: Host Mode

Before initiating any Bulk IN Transactions in Host mode:

- The HOST\_RXTYPE register for the endpoint that is to be used needs to be programmed as:
  - Operating speed in the SPEED bit field (bits 7 and 6).
  - Set 10 (binary value) in the PROT field for bulk transfer.
  - Endpoint Number of the target device in RENDPN field. This is the endpoint number contained in the Rx endpoint descriptor returned by the target device during enumeration.
- The RXMAXP register for the controller endpoint must be written with the maximum packet size (in bytes) for the transfer. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the target endpoint.
- The HOST\_RXINTERVAL register needs to be written with the required value for the NAK limit (2-215 frames/microframes), or set to zero if the NAK timeout feature is not required.
- The relevant interrupt enable bit in the INTRRXE register should be set (if an interrupt is required for this endpoint).

**Note:** Whether interrupt is handled from PDR level or Core level, interrupt is required to be enabled at the core level. See details on Core Interrupt registers, CTRLR register, and sections on Interrupt Handling

- The AUTOREQ bit field should be used only when servicing transfers using CPU mode and must be cleared when using DMA Mode. For DMA Mode, dedicated registers USB0/1 Req Registers exist and the HOST\_RXCSR[AUTOREQ] should be cleared.

When DMA is enabled, the following bits of HOST\_RXCSR register should be set as:

- Clear AUTOCLEAR.
- Set DMAEN (bit 13) to 1 if a DMA request is required for this endpoint.
- Clear DSINYET (bit 12) to 0 to allow normal PING flow control. This will affect only High Speed transactions.
- Clear DMAMODE (bit 11) to 0.

**Note:** If DMA is enabled, the USB0/1 Auto Req register can be set for generating IN tokens automatically after receiving the data. Set the bit field RXn\_AUTOREQ (where n is the endpoint number) with binary value 01 or 11.

When the endpoint is first configured, the endpoint data toggle should be cleared to 0 either by using the DATATOGWREN and DATATOG bits of HOST\_RXCSR (bit 10 and bit 9) to toggle the current setting or by setting the CLRDATATOG bit of HOST\_RXCSR (bit 7). This will ensure that the data toggle (which is handled automatically by the controller) starts in the correct state. Also if there are any data packets in the FIFO (indicated by the RXPBKTRDY bit (bit 0 of HOST\_RXCSR) being set), they should be flushed by setting the FLUSHFIFO bit of HOST\_RXCSR (bit 4).

**NOTE:** It may be necessary to set this bit twice in succession if double buffering is enabled.

#### 16.3.8.2.2.1.2 Bulk IN Operation: Host Mode

When Bulk data is required from the USB peripheral device, the software should set the REQPKT bit in the corresponding HOST\_RXCSR register (bit 5). The controller will then send an IN token to the selected peripheral endpoint and waits for data to be returned.

If data is correctly received, RXPBKTRDY bit of HOST\_RXCSR (bit 0) is set. If the USB peripheral device responds with a STALL, RXSTALL bit (bit 6 of HOST\_RXCSR) is set. If a NAK is received, the controller tries again and continues to try until either the transaction is successful or the POLINTVL\_NAKLIMIT set in the HOST\_RXINTERVAL register is reached. If no response at all is received, two further attempts are made before the controller reports an error by setting the ERROR bit of HOST\_RXCSR (bit 2).

The controller then generates the appropriate endpoint interrupt, whereupon the software should read the corresponding HOST\_RXCSR register to determine whether the RXPBKTRDY, RXSTALL, ERROR or DATAERR\_NAKTIMEOUT bit is set and act accordingly. If the DATAERR\_NAKTIMEOUT bit is set, the controller can be directed either to continue trying this transaction (until it times out again) by clearing the DATAERR\_NAKTIMEOUT bit or to abort the transaction by clearing REQPKT bit before clearing the DATAERR\_NAKTIMEOUT bit.

The packets received should not exceed the size specified in the RXMAXP register (as this should be the value set in the wMaxPacketSize field of the endpoint descriptor sent to the host).

In the general case, the application software (if CPU is servicing the endpoint) will need to read each packet from the FIFO individually. If large blocks of data are being transferred, the overhead of calling an interrupt service routine to unload each packet can be avoided by using DMA.

**Note:** When using DMA, see [Section 16.3.9, Communications Port Programming Interface \(CPPI\) 4.1 DMA](#), for the proper configuration of the core register, HOST\_RXCSR.

#### 16.3.8.2.2.1.3 Bulk IN Error Handling: Host Mode

If the target wants to shut down the Bulk IN pipe, it will send a STALL response to the IN token. This will result in the RXSTALL bit of HOST\_RXCSR (bit 6) being set.

#### 16.3.8.2.2.2 Bulk OUT Transactions: Host Mode

A Bulk OUT transaction may be used to transfer non-periodic data from the host to the USB peripheral.

Following optional features are available for use with a Tx endpoint used in Host mode to transmit this data:

- Double packet buffering: When enabled, up to two packets can be stored in the FIFO awaiting transmission to the peripheral device. Double packet buffering is enabled by setting the DPB bit of TXFIFOSZ register (bit 4).
- DMA: If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint is able to accept another packet in its FIFO. This feature can be used to allow the DMA controller to load packets into the FIFO without processor intervention. For more information on using DMA, consult the section discussing CPPI DMA.

When DMA is enabled and DMAMODE bit in HOST\_TXCSR register is set, an endpoint interrupt will not be generated for completion of packet reception. An endpoint interrupt will be generated only in the error conditions.

### 16.3.8.2.2.1 Bulk OUT Setup: Host Mode

Before initiating any bulk OUT transactions:

- The target function address needs to be set in the TXFUNCADDR register for the selected controller endpoint. (TXFUNCADDR register is available for all endpoints from EP0 to EP15.)
- The HOST\_TXTYPE register for the endpoint that is to be used needs to be programmed as:
  - Operating speed in the SPEED bit field (bits 7 and 6).
  - Set PROT field to 10b for bulk transfer.
  - Enter Endpoint Number of the target device in TENDPN field. This is the endpoint number contained in the OUT(Tx) endpoint descriptor returned by the target device during enumeration.
- The TXMAXP register for the controller endpoint must be written with the maximum packet size (in bytes) for the transfer. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the target endpoint.
- The HOST\_TXINTERVAL register needs to be written with the required value for the NAK limit (2-215 frames/microframes), or set to zero if the NAK timeout feature is not required.
- The relevant interrupt enable bit in the INTRTXE register should be set (if an interrupt is required for this endpoint).
- The following bits of HOST\_TXCSR register should be set as:
  - Set the MODE bit (bit 13) to 1 to ensure the FIFO is enabled (only necessary if the FIFO is shared with an Rx endpoint).
  - Clear the FRCDATATOG bit (bit 11) to 0 to allow normal data toggle operations.
  - Clear/Set AUTOSET bit (bit 15). The setting of this bit depends on the desire of the user/application in automatically setting the TXPKTRDY bit when servicing transactions using CPU.

**Note:** If DMA is needs to be used in place of the CPU, the following table displays the setting of the core register HOST\_TXCSR register in Host mode. For the CPPI DMA registers settings consult the section on CPPI DMA within this document.

Bit Field	Bit Name	Description
Bit 15	AUTOSET	Cleared to 0 if using DMA. For CPU Mode use, if AUTOSET bit is set, the TXPKTRDY bit will be automatically set when data of the maximum packet size is loaded into the FIFO.
Bit 14	ISO	Cleared to 0 for bulk mode operation.
Bit 13	MODE	Set to 1 to make sure the FIFO is enabled (only necessary if the FIFO is shared with an RX endpoint)
Bit 12	DMAEN	Set to 1 to enable DMA usage; not needed if CPU is being used to service the Tx Endpoint
Bit 11	FRCDATATOG	Cleared to 0 to allow normal data toggle operations.
Bit 10	DMAMODE	Set to 1 when DMA is used to service Tx FIFO.

When the endpoint is first configured, the endpoint data toggle should be cleared to 0 either by using the DATATOGWREN bit and DATATOG bit of HOST\_TXCSR (bit 9 and bit 8) to toggle the current setting or by setting the CLRDATATOG bit of HOST\_TXCSR (bit 6). This will ensure that the data toggle (which is handled automatically by the controller) starts in the correct state. Also, if there are any data packets in the FIFO (indicated by the FIFONOTEMPTY bit of HOST\_TXCSR register (bit 1) being set), they should be flushed by setting the FLUSHFIFO bit (bit 3 of HOST\_TXCSR).

**NOTE:** It may be necessary to set this bit twice in succession if double buffering is enabled.

#### 16.3.8.2.2.2 Bulk OUT Operation: Host Mode

When Bulk data is required to be sent to the USB peripheral device, the software should write the first packet of the data to the FIFO (or two packets if double-buffered) and set the TXPKTRDY bit in the corresponding HOST\_TXCSR register (bit 0). The controller will then send an OUT token to the selected peripheral endpoint, followed by the first data packet from the FIFO.

If data is correctly received by the peripheral device, an ACK should be received whereupon the controller will clear TXPKTRDY bit of HOST\_TXCSR (bit 0). If the USB peripheral device responds with a STALL, the RXSTALL bit (bit 5) of HOST\_TXCSR is set. If a NAK is received, the controller tries again and continues to try until either the transaction is successful or the NAK limit set in the HOST\_TXINTERVAL register is reached. If no response at all is received, two further attempts are made before the controller reports an error by setting ERROR bit in HOST\_TXCSR (bit 2).

The controller then generates the appropriate endpoint interrupt, whereupon the software should read the corresponding HOST\_TXCSR register to determine whether the RXSTALL (bit 5), ERROR (bit 2) or NAK\_TIMEOUT (bit 7) bit is set and act accordingly. If the NAK\_TIMEOUT bit is set, the controller can be directed either to continue trying this transaction (until it times out again) by clearing the NAK\_TIMEOUT bit or to abort the transaction by flushing the FIFO before clearing the NAK\_TIMEOUT bit.

If large blocks of data are being transferred, then the overhead of calling an interrupt service routine to load each packet can be avoided by using DMA.

#### 16.3.8.2.2.3 Bulk OUT Error Handling: Host Mode

If the target wants to shut down the Bulk OUT pipe, it will send a STALL response. This is indicated by the RXSTALL bit of HOST\_TXCSR register (bit 5) being set.

#### 16.3.8.2.3 Interrupt Transfer: Host Mode

When the controller is operating as the host, interactions with an Interrupt endpoint on the USB peripheral device are handled in very much the same way as the equivalent Bulk transactions (described in previous sections).

The principal difference as far as operational steps are concerned is that the PROT field of HOST\_RXTYPE and HOST\_TXTYPE (bits 5-4) need to be set (binary value) to represent an Interrupt transaction. The required polling interval also needs to be set in the HOST\_RXINTERVAL and HOST\_TXINTERVAL registers.

#### 16.3.8.2.4 Isochronous Transfer: Host Mode

Isochronous transfers are used when working with isochronous data. Isochronous transfers provide periodic, continuous communication between host and device.

An Isochronous IN transaction is used to transfer periodic data from the USB peripheral to the host.

##### 16.3.8.2.4.1 Isochronous IN Transactions: Host Mode

The following optional features are available for use with an Rx endpoint used in Host mode to receive this data:

- Double packet buffering: When enabled, up to two packets can be stored in the FIFO on reception from the host. This allows that one packet can be received while another is being read. Double packet buffering is enabled by setting the DPB bit of RXFIFOSZ register (bit 4).
- AutoRequest: When the AutoRequest feature is enabled, the REQPKT bit of HOST\_RXCSR (bit 5) will be automatically set when the RXPKTRDY bit is cleared. This only applies when the CPU is being used to service the endpoint. When using DMA, this bit field needs to be cleared to Zero. CPPI DMA has its own configuration registers that renders a similar task, USB0/1 Auto Req registers, that needs to be used to have a similar effect. For more information, see [Section 16.3.9, Communications Port Programming Interface \(CPPI\) 4.1 DMA](#).
- DMA: If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint has a packet in its FIFO. This feature can be used to allow the DMA controller to unload packets from the FIFO without processor intervention. However, this feature is not particularly useful with isochronous

endpoints because the packets transferred are often not maximum packet size.

- When DMA is enabled, endpoint interrupt will not be generated for completion of packet reception. Endpoint interrupt will be generated only in the error conditions.

#### **16.3.8.2.4.1.1 Isochronous IN Transfer Setup: Host**

Before initiating an Isochronous IN Transactions in Host mode:

- The target function address needs to be set in the RXFUNCADDR register for the selected controller endpoint (RXFUNCADDR register is available for all endpoints from EP0 to EP4).
- The HOST\_RXTYPE register for the endpoint that is to be used needs to be programmed as:
  - Operating speed in the SPEED bit field (bits 7 and 6).
  - Set 01 (binary value) in the PROT field for isochronous transfer.
  - Endpoint Number of the target device in RENDPN field. This is the endpoint number contained in the Rx endpoint descriptor returned by the target device during enumeration.
- The RXMAXP register for the controller endpoint must be written with the maximum packet size (in bytes) for the transfer. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the target endpoint.
- The HOST\_RXINTERVAL register needs to be written with the required transaction interval (usually one transaction per frame/microframe).
- The relevant interrupt enable bit in the INTRRXE register should be set (if an interrupt is required for this endpoint).
- The following bits of HOST\_RXCSR register should be set as:
  - Clear AUTOCLEAR
  - Set the DMAEN bit (bit 13) to 1 if a DMA request is required for this endpoint.
  - Clear the DISNYET it (bit 12) to 0 to allow normal PING flow control. This will only affect High Speed transactions.
  - Clear DMAMODE bit (bit 11) to 0.
- If DMA is enabled, AUTOREQ register can be set for generating IN tokens automatically after receiving the data. Set the bit field RXn\_AUTOREQ (where n is the endpoint number) with binary value 01 or 11. For detailed information on using CPPI DMA, consult related section within this document.

#### **16.3.8.2.4.1.2 Isochronous IN Operation: Host Mode**

The operation starts with the software setting REQPKT bit of HOST\_RXCSR (bit 5). This causes the controller to send an IN token to the target.

When a packet is received, an interrupt is generated which the software may use to unload the packet from the FIFO and clear the RXPKTRDY bit in the HOST\_RXCSR register (bit 0) in the same way as for a Bulk Rx endpoint. As the interrupt could occur almost any time within a frame(/microframe), the timing of FIFO unload requests will probably be irregular. If the data sink for the endpoint is going to some external hardware, it may be better to minimize the requirement for additional buffering by waiting until the end of each frame before unloading the FIFO. This can be done by using the SOF\_PULSE signal from the controller to trigger the unloading of the data packet. The SOF\_PULSE is generated once per frame(/microframe). The interrupts may still be used to clear the RXPKTRDY bit in HOST\_RXCSR.

#### **16.3.8.2.4.1.3 Isochronous IN Error Handling: Host Mode**

If a CRC or bit-stuff error occurs during the reception of a packet, the packet will still be stored in the FIFO but the DATAERR\_NAKTIMEOUT bit of HOST\_RXCSR (bit 3) is set to indicate that the data may be corrupt.

**Note:** The number of USB packets sent in any microframe will depend on the amount of data to be transferred, and is indicated through the PIDs used for the individual packets. If the indicated numbers of packets have not been received by the end of a microframe, the INCOMPRX bit in the HOST\_RXCSR register will be set to indicate that the data in the FIFO is incomplete. Equally, if a packet of the wrong data type is received, then the PID Error bit in the HOST\_RXCSR register will be set. In each case, an interrupt will, however, still be generated to allow the data that has been received to be read from the FIFO.

#### 16.3.8.2.4.2 Isochronous OUT Transactions: Host Mode

An Isochronous OUT transaction may be used to transfer periodic data from the host to the USB peripheral.

Following optional features are available for use with a Tx endpoint used in Host mode to transmit this data:

- Double packet buffering: When enabled, up to two packets can be stored in the FIFO awaiting transmission to the peripheral device. Double packet buffering is enabled by setting the DPB bit of TXFIFOSZ register (bit 4).

DMA: If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint is able to accept another packet in its FIFO. This feature can be used to allow the DMA controller to load packets into the FIFO without processor intervention.

However, this feature is not particularly useful with isochronous endpoints because the packets transferred are often not maximum packet size.

When DMA is enabled and endpoint interrupt will not be generated for completion of packet reception. Endpoint interrupt will be generated only in the error conditions.

##### 16.3.8.2.4.2.1 Isochronous OUT Transfer Setup: Host Mode

Before initiating any Isochronous OUT transactions:

- The target function address needs to be set in the TXFUNCADDR register for the selected controller endpoint (TXFUNCADDR register is available for all endpoints from EP0 to EP4).
- The HOST\_TXTYPE register for the endpoint that is to be used needs to be programmed as:
  - Operating speed in the SPEED bit field (bits 7 and 6).
  - Set 01 (binary value) in the PROT field for isochronous transfer.
  - Endpoint Number of the target device in TENDPN field. This is the endpoint number contained in the OUT(Tx) endpoint descriptor returned by the target device during enumeration.
- The TXMAXP register for the controller endpoint must be written with the maximum packet size (in bytes) for the transfer. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the target endpoint.
- The HOST\_TXINTERVAL register needs to be written with the required transaction interval (usually one transaction per frame/microframe).
- The relevant interrupt enable bit in the INTRTXE register should be set (if an interrupt is required for this endpoint).
- The following bits of HOST\_TXCSR register should be set as:
  - Set the MODE bit (bit 13) to 1 to ensure the FIFO is enabled (only necessary if the FIFO is shared with an Rx endpoint).
  - Set the DMAEN bit (bit 12) to 1 if a DMA request is required for this endpoint
  - The FRCDATATOG bit (bit 11) is ignored for isochronous transactions.
  - Set the DMAMODE bit (bit 10) to 1 when DMA is enabled.
 For more details in using DMA, consult CPPI DMA section within this document.

##### 16.3.8.2.4.2.2 Isochronous OUT Transfer Operation: Host Mode

The operation starts when the software writes to the FIFO and sets TXPKTRDY bit of HOST\_TXCSR (bit 0). This triggers the controller to send an OUT token followed by the first data packet from the FIFO.

An interrupt is generated whenever a packet is sent and the software may use this interrupt to load the next packet into the FIFO and set the TXPKTRDY bit in the HOST\_TXCSR register (bit 0) in the same way as for a Bulk Tx endpoint. As the interrupt could occur almost any time within a frame, depending on when the host has scheduled the transaction, this may result in irregular timing of FIFO load requests. If the data source for the endpoint is coming from some external hardware, it may be more convenient to wait until the end of each frame before loading the FIFO as this will minimize the requirement for additional buffering. This can be done by using the SOF\_PULSE signal from the controller to trigger the loading of the next data packet. The SOF\_PULSE is generated once per frame(/microframe). The interrupts may still be used to set the TXPKTRDY bit in HOST\_TXCSR.

### 16.3.9 Communications Port Programming Interface (CPPI) 4.1 DMA

The CPPI DMA module supports the transmission and reception of USB packets. The CPPI DMA is designed to facilitate the segmentation and reassembly of CPPI compliant packets to/from smaller data blocks that are natively compatible with the specific requirements of each networking port. Multiple Tx and Rx channels are provided for all endpoints (excluding endpoint 0) within the DMA allowing multiple segmentation or reassembly operations to be effectively performed in parallel (but not actually simultaneously). The DMA controller maintains state information for each of the ports/channels which allows packet segmentation and reassembly operations to be time division multiplexed between channels in order to share the underlying DMA hardware. A DMA scheduler is used to control the ordering and rate at which this multiplexing occurs.

The CPPI (version 4.1) DMA controller sub-module is a common 15 port DMA controller. It supports 15 Tx and 15 Rx channels and each port attaches to the associated endpoint in the controller. Port 1 maps to endpoint 1 and Port 2 maps to endpoint 2 and so on with Port 15 mapped to endpoint 15; endpoint 0 can not utilize the DMA and the firmware is responsible to load or offload the endpoint 0 FIFO via CPU.

#### 16.3.9.1 CPPI Terminology

**Host** — The host is an intelligent system resource that configures and manages each communications control module. The host is responsible for allocating memory, initializing all data structures, and responding to port interrupts.

**Main Memory** — The area of data storage managed by the CPU. The CPPI DMA (CDMA) reads and writes CPPI packets from and to main memory. This memory can exist internal or external from the device.

**Queue Manager (QM)** — The QM is responsible for accelerating management of a variety of Packet Queues and Free Descriptor / Buffer Queues. It provides status indications to the CDMA Scheduler when queues are empty or full.

**CPPI DMA (CDMA)** — The CDMA is responsible for transferring data between the CPPI FIFO and Main Memory. It acquires free Buffer Descriptor from the QM (Receive Submit Queue) for storage of received data, posts received packets pointers to the Receive Completion Queue, transmits packets stored on the Transmit Submit Queue (Transmit Queue), and posts completed transmit packets to the Transmit Completion Queue.

**CDMA Scheduler (CDMAS)** — The CDMAS is responsible for scheduling CDMA transmit and receive operations. It uses Queue Indicators from the QM and the CDMA to determine the types of operations to schedule.

**CPPI FIFO** — The CPPI FIFO provides FIFO interfaces (for each of the 15 transmit and 15 receive endpoints).

**Transfer DMA (XDMA)** — The XDMA receives DMA requests from the Mentor USB 2.0 Core and initiates DMAs to the CPPI FIFO.

**Endpoint FIFOs** — The Endpoint FIFOs are the USB packet storage elements used by the Mentor USB 2.0 Core for packet transmission or reception. The XDMA transfers data between the CPPI FIFO and the Endpoint FIFOs for transmit operations and between the Endpoint FIFOs and the CPPI FIFO for receive operations.

**Port** — A port is the communications module (peripheral hardware) that contains the control logic for Direct Memory Access for a single transmit/receive interface or set of interfaces. Each port may have multiple communication channels that transfer data using homogenous or heterogeneous protocols. A port is usually subdivided into transmit and receive pairs which are independent of each other. Each endpoint, excluding endpoint 0, has its own dedicated port.

**Channel** — A channel refers to the sub-division of information (flows) that is transported across ports. Each channel has associated state information. Channels are used to segregate information flows based on the protocol used, scheduling requirements (example: CBR, VBR, ABR), or concurrency requirements (that is, blocking avoidance). All fifteen ports per USB Module have dedicated single channels, channel 0, associated for their use in a USB application.

**Data Buffer** — A data buffer is a single data structure that contains payload information for transmission to or reception from a port. A data buffer is a byte aligned contiguous block of memory used to store packet payload data. A data buffer may hold any portion of a packet and may be linked together (via descriptors) with other buffers to form packets. Data buffers may be allocated anywhere within the 32-bit memory space. The Buffer Length field of the packet descriptor indicates the number of valid data bytes in the buffer. There may be from 1 to 4M-1 valid data bytes in each buffer.

**Host Buffer Descriptor (Buffer Descriptor)** — A buffer descriptor is a single data structure that contains information about one or more data buffers. This type of descriptor is required when more than one descriptor is needed to define an entire packet, i.e., it either defines the middle of a packet or end of a packet.

**Start of Packet (SOP)** — Packet along side Buffer Descriptors are used to hold information about Packets. When multiple Descriptors are used to hold a single packet information or a single Descriptor is used to hold a single packet information, the first descriptor is referred to as a Packet Descriptor which is also Start-of-Packet Descriptor.

**Host Packet Descriptor (Packet Descriptor)** — A packet descriptor is another name for the first buffer descriptor within a packet. Some fields within a data buffer descriptor are only valid when it is a packet descriptor including the tags, packet length, packet type, and flags. This type of descriptor is always used to define a packet since it provides packet level information that is useful to both the ports and the Host in order to properly process the packet. It is the only descriptor used when single descriptor solely defines a packet. When multiple descriptors are needed to define a packet, the packet descriptor is the first descriptor used to define a packet.

**Free Descriptor/Buffer Queue** — A free descriptor/buffer queue is a hardware managed list of available descriptors with pre-linked empty buffers that are to be used by the receive ports for host type descriptors. Free Descriptor/Buffer Queues are implemented by the Queue Manager.

**Teardown Descriptor** — Teardown Descriptor is a special structure which is not used to describe either a packet or a buffer but is instead used to describe the completion of a channel halt and teardown event. Channel teardown is an important function because it ensures that when a connection is no longer needed that the hardware can be reliably halted and any remaining packets which had not yet been transmitted can be reclaimed by the Host without the possibility of losing buffer or descriptor references (which results in a memory leak).

**Packet Queue** — A packet queue is hardware managed list of valid (i.e. populated) packet descriptors that is used for forwarding a packet from one entity to another for any number of purposes.

**NOTE:** All descriptors (regardless of type) must be allocated at addresses that are naturally aligned to the smallest power of 2 that is equal to or greater than the descriptor size.

### 16.3.9.2 Data Structures

Two data structures are mainly used to identify data buffers used by packet and buffer descriptors. A third Descriptor, Teardown Descriptor, exists. The purpose of this Descriptor is a channel halt and teardown event. Each of these Descriptor layouts as well as bit fields are shown below.

#### 16.3.9.2.1 Host Packet Descriptor/ Packet Descriptor (SOP Descriptor)

Descriptors are designed to be used when USB like application requires support for true, unlimited fragment count scatter/gather type operations. The Packet Descriptor is the first descriptor on multiple descriptors setup or the only descriptor in a single descriptors setup. The Packet Descriptor contains the following information:

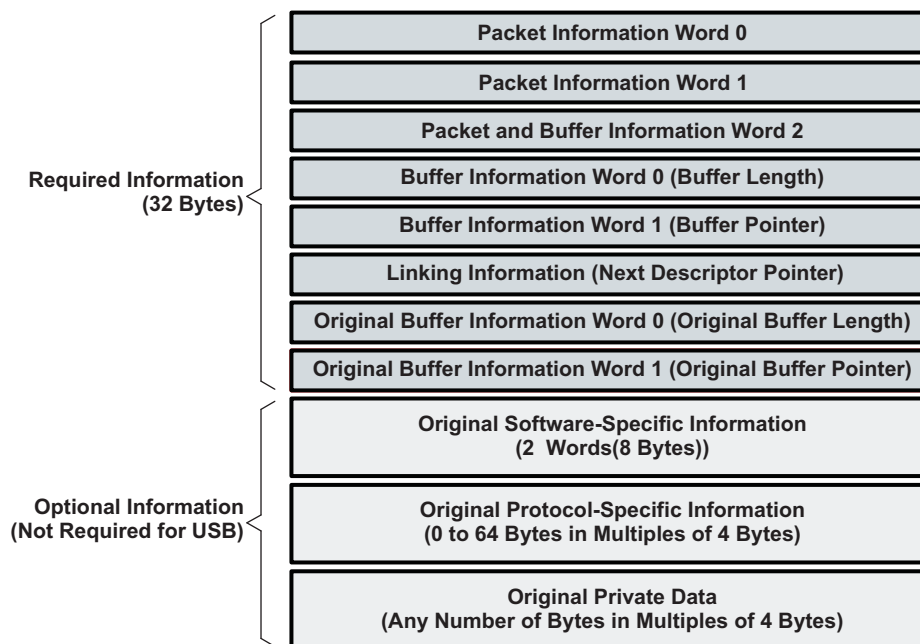

- Indicator which identifies the descriptor as a packet descriptor (always 10h)
- Source and destination tags (reserved)
- Packet type
- Packet length
- Protocol specific region size
- Protocol specific control/statusbits
- Pointer to the first valid byte in the SOP data buffer

- Length of the SOP data buffer
- Pointer to the next buffer descriptor in the

Packet descriptors can vary in size by design of their defined fields from 32 bytes up to 104 bytes. Within this range, packet descriptors always contain 32 bytes of required information and may also contain 8 bytes of software specific tagging information and up to 64 bytes (indicated in 4 byte increments) of protocol specific information. How much protocol specific information (and therefore the allocated size of the descriptors) is application dependent. Port will make use of the first 32 bytes only.

From a general USB use perspective, a 32-byte descriptor size is suffix and the use of this size is expected for a normal USB usage.

The packet descriptor layout is shown in [Figure 16-13](#) and described within [Table 16-9](#) through [Table 16-16](#).

**Figure 16-13. Packet Descriptor Layout**

**Table 16-9. Packet Descriptor Word 0 (PD0) Bit Field Descriptions**

Bits	Field Name	Description
31-27	Descriptor type	The host packet descriptor type is 16 decimal (10h). The CPU initializes this field.
26-22	Protocol-specific valid word count	This field indicates the valid number of 32-bit words in the protocol-specific region. The CPU initializes this field. This is encoded in increments of 4 bytes as: 0 = 0 byte 1 = 4 bytes ... 16 = 64 bytes 17-31 = Reserved
21-0	Packet length	The length of the packet in bytes. If the packet length is less than the sum of the buffer lengths, then the packet data will be truncated. A packet length greater than the sum of the buffers is an error. The valid range for the packet length is 0 to (4M - 1) bytes. The CPU initializes this field for transmitted packets; the DMA overwrites this field on packet reception.

**Table 16-10. Packet Descriptor Word 1 (PD1) Bit Field Descriptions**

Bits	Field Name	Description
31-27	Source Tag; Port #	This field indicates the port number (0-31) from which the packet originated. The DMA overwrites this field on packet reception. This is the RX Endpoint number from which the packet originated.
26-21	Source Tag; Channel #	This field indicates the channel number within the port from which the packet originated. The DMA overwrites this field on packet reception. This field is always 0-67.
20-16	Source Tag; Sub-channel #	This field indicates the sub-channel number (0-31) within the channel from which the packet originated. The DMA overwrites this field on packet reception. This field is always 0.
15-0	Destination Tag	This field is application-specific. This field is always 0.

**Table 16-11. Packet Descriptor Word 2 (PD2) Bit Field Descriptions**

Bits	Field Name	Description
31	Packet error	This bit indicates if an error occurred during reception of this packet (0 = no error occurred; 1 = error occurred). The DMA overwrites this field on packet reception. Additional information about different errors may be encoded in the protocol specific fields in the descriptor.
30-26		This field indicates the type of this packet. The CPU initializes this field for transmitted packets; the DMA overwrites this field on packet reception. This field is encoded as: 5 = USB 8-31 = Reserved
25-20	Reserved	Reserved
19	Zero-length packet indicator	If a zero-length USB packet is received, the XDMA will send the CDMA a data block with a byte count of 0 and this bit is set. The CDMA will then perform normal EOP termination of the packet without transferring data. For transmit, if a packet has this bit set, the XDMA will ignore the CPPI packet size and send a zero-length packet to the USB controller.
18-16	Protocol-specific	This field contains protocol-specific flags/information that can be assigned based on the packet type. Not used for USB.
15	Return policy	This field indicates the return policy for this packet. The CPU initializes this field. 0 = Entire packet (still linked together) should be returned to the queue specified in bits 11-0. 1 = Each buffer should be returned to the queue specified in bits 11-0 of Word 2 in their respective descriptors. The Tx DMA will return each buffer in sequence.
14	On-chip	This field indicates whether or not this descriptor is in a region which is in on-chip memory space (1) or in external memory (0).
13-12	Packet return queue mgr #	This field indicates which queue manager in the system the descriptor is to be returned to after transmission is complete. This field is not altered by the DMA during transmission or reception and is initialized by the CPU. There is only one queue manager in the USB HS/FS device controller. This field must always be 0.
11-0	Packet return queue #	This field indicates the queue number within the selected queue manager that the descriptor is to be returned to after transmission is complete. This field is not altered by the DMA during transmission or reception and is initialized by the CPU.

**Table 16-12. Packet Descriptor Word 3 (PD3) Bit Field Descriptions**

Bits	Field Name	Description
31-22	Reserved	Reserved
21-0	Buffer 0 length	The buffer length field indicates how many valid data bytes are in the buffer. The CPU initializes this field for transmitted packets; the DMA overwrites this field on packet reception.

**Table 16-13. Packet Descriptor Word 4 (PD4) Bit Field Descriptions**

Bits	Field Name	Description
31-0	Buffer 0 pointer	The buffer pointer is the byte-aligned memory address of the buffer associated with the buffer descriptor. The CPU initializes this field for transmitted packets; the DMA overwrites this field on packet reception.

**Table 16-14. Packet Descriptor Word 5 (PD5) Bit Field Descriptions**

Bits	Field Name	Description
31-0	Next descriptor pointer	The 32-bit word aligned memory address of the next buffer descriptor in the packet. If the value of this pointer is zero, then the current buffer is the last buffer in the packet. The CPU initializes this field for transmitted packets; the DMA overwrites this field on packet reception.

**Table 16-15. Packet Descriptor Word 6 (PD6) Bit Field Descriptions**

Bits	Field Name	Description
31-22	Reserved	Reserved
21-0	Original buffer 0 length	The buffer length field indicates the original size of the buffer in bytes. This value is not overwritten during reception. This value is read by the Rx DMA to determine the actual buffer size as allocated by the CPU at initialization. Since the buffer length in Word 3 is overwritten by the Rx port during reception, this field is necessary to permanently store the buffer size information.

**Table 16-16. Packet Descriptor Word 7 (PD7) Bit Field Descriptions**

Bits	Field Name	Description
31-22	Reserved	Reserved
21-0	Original buffer 0 pointer	The buffer pointer is the byte-aligned memory address of the buffer associated with the buffer descriptor. This value is not overwritten during reception. This value is read by the Rx DMA to determine the actual buffer location as allocated by the CPU at initialization. Since the buffer pointer in Word 4 is overwritten by the Rx port during reception, this field is necessary to permanently store the buffer pointer information.

### 16.3.9.2.2 Host Buffer Descriptor/Buffer Descriptor (BD)

The buffer descriptor is identical in size and organization to a Packet Descriptor but does not include valid information in the packet level fields and does not include a populated region for protocol specific information. The packet level fields are not needed since the SOP descriptor contains this information and additional copy of this data is not needed/necessary.

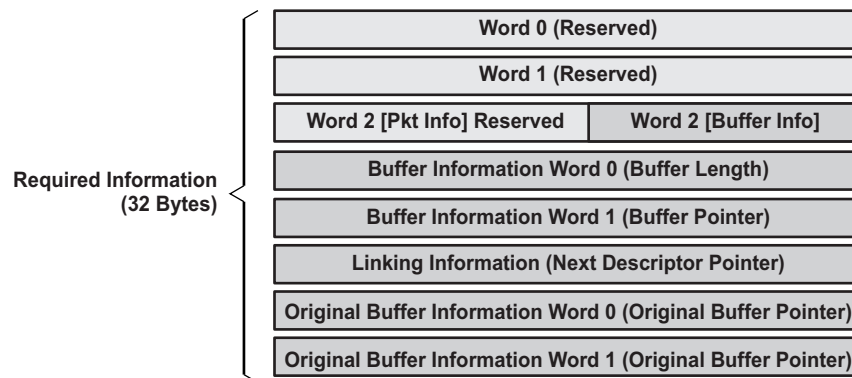

Host buffer descriptors are designed to be linked onto a host packet descriptor or another host buffer descriptor to provide support for unlimited scatter / gather type operations. Host buffer descriptors provide information about a single corresponding data buffer. Every host buffer descriptor stores the following information:

- Pointer to the first valid byte in the data
- Length of the data buffer
- Pointer to the next buffer descriptor in the packet

Buffer descriptors always contain 32 bytes of required information. Since it is a requirement that it is possible to convert a descriptor between a Buffer Descriptor and a Packet Descriptor (by filling in the appropriate fields) in practice, Buffer Descriptors will be allocated using the same sizes as Packet Descriptors. In addition, since the 5 LSBs of the Descriptor Pointers are used in CPPI 4.1 for the purpose of indicating the length of the descriptor, the minimum size of a descriptor is always 32 bytes

The buffer descriptor layout is shown in [Figure 16-14](#) and described within [Table 16-17](#) through [Table 16-24](#).

**Figure 16-14. Buffer Descriptor (BD) Layout**

**Table 16-17. Buffer Descriptor Word 0 (BD0) Bit Field Descriptions**

Bits	Field Name	Description
31-0	Reserved	Reserved

**Table 16-18. Buffer Descriptor Word 1 (BD1) Bit Field Descriptions**

Bits	Field Name	Description
31-0	Reserved	Reserved

**Table 16-19. Buffer Descriptor Word 2 (BD2) Bit Field Descriptions**

Bits	Field Name	Description
31-15	Reserved	Reserved
14	On-chip	This field indicates whether or not this descriptor is in a region which is on-chip memory space (1) or in external memory (0).
13-12	Packet return queue mgr #	This field indicates which queue manager in the system the descriptor is to be returned to after transmission is complete. This field is not altered by the DMA during transmission or reception and is initialized by the CPU. There is only 1 queue manager in the USB HS/FS device controller. This field must always be 0.
11-0	Packet return queue #	This field indicates the queue number within the selected queue manager that the descriptor is to be returned to after transmission is complete. This field is not altered by the DMA during transmission or reception and is initialized by the CPU.

**Table 16-20. Buffer Descriptor Word 3 (BD3) Bit Field Descriptions**

Bits	Field Name	Description
31-22	Reserved	Reserved
21-0	Buffer 0 length	The buffer length field indicates how many valid data bytes are in the buffer. The CPU initializes this field for transmitted packets. The DMA overwrites this field upon packet reception.

**Table 16-21. Buffer Descriptor Word 4 (BD4) Bit Field Descriptions**

Bits	Field Name	Description
31-0	Buffer 0 pointer	The buffer pointer is the byte-aligned memory address of the buffer associated with the buffer descriptor. The CPU initializes this field for transmitted packets. The DMA overwrites this field upon packet reception.

**Table 16-22. Buffer Descriptor Word 5 (BD5) Bit Field Descriptions**

Bits	Field Name	Description
31-0	Next description pointer	The 32-bit word aligned memory address of the next buffer descriptor in the packet. If the value of this pointer is zero, then the current descriptor is the last descriptor in the packet. The CPU initializes this field for transmitted packets. The DMA overwrites this field upon packet reception.

**Table 16-23. Buffer Descriptor Word 6 (BD6) Bit Field Descriptions**

Bits	Field Name	Description
31-22	Reserved	Reserved
21-0	Original buffer 0 length	The buffer length field indicates the original size of the buffer in bytes. This value is not overwritten during reception. This value is read by the Rx DMA to determine the actual buffer size as allocated by the CPU at initialization. Since the buffer length in Word 3 is overwritten by the Rx port during reception, this field is necessary to permanently store the buffer size information.

**Table 16-24. Buffer Descriptor Word 7 (BD7) Bit Field Descriptions**

Bits	Field Name	Description
31-0	Original buffer 0 pointer	The buffer pointer is the byte-aligned memory address of the buffer associated with the buffer descriptor. This value is not overwritten during reception. This value is read by the Rx DMA to determine the actual buffer location as allocated by the CPU at initialization. Since the buffer pointer in Word 4 is overwritten by the Rx port during reception, this field is necessary to permanently store the buffer pointer information.

### 16.3.9.2.3 Teardown Descriptor

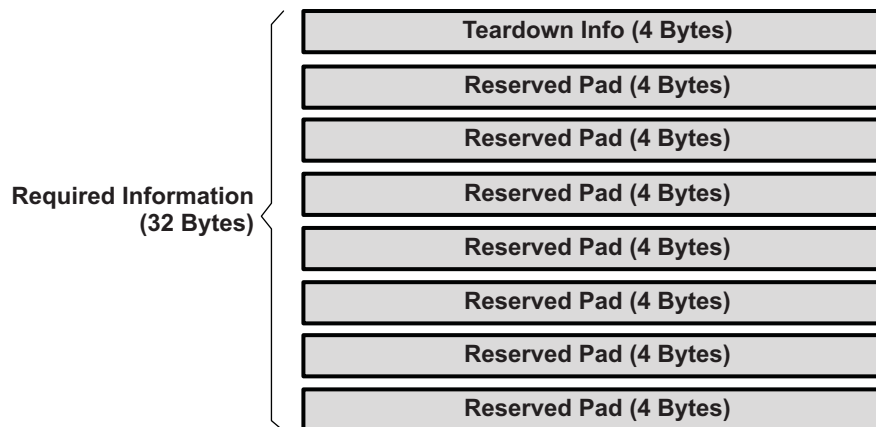

The Teardown Descriptor is not like the packet or buffer descriptors since it is not used to describe either a packet or a buffer. The teardown descriptor is always 32 bytes long and is comprised of 4 bytes of actual teardown information and 28 bytes of pad. The teardown descriptor layout and associated bit field descriptions are shown in the Figure below and Tables that follows. Since the 5 LSBs of the descriptor pointers are used in CPPI 4.1 for the purpose of indicating the length of the descriptor, the minimum size of a descriptor is 32 bytes.

The teardown descriptor is used to describe a channel halt and teardown event. Channel teardown ensures that when a connection is no longer needed that the hardware can be reliably halted and any remaining packets which had not yet been transmitted can be reclaimed by the host without the possibility of losing buffer or descriptor references (which results in a memory leak).

The teardown descriptor contains the following information:

- Indicator which identifies the descriptor as a teardown packet descriptor
- DMA controller number where teardown
- Channel number within DMA where teardown occurred
- Indicator of whether this teardown was for the Tx or Rx channel

**Figure 16-15. Teardown Descriptor Layout**

**Table 16-25. Teardown Descriptor Word 0 Bit Field Descriptions**

Bits	Field Name	Description
31-27	Descriptor type	The teardown descriptor type is 19 decimal (13h)
26-17	Reserved	Reserved
16	TX_RX	Indicates whether teardown is a TX (0) or RX (1).
15-10	DMA number	Indicates the DMA number for this teardown.
9-6	Reserved	Reserved
5-0	Channel number	Indicates the channel number within the DMA that was torn down.

**Table 16-26. Teardown Descriptor Words 1 to 7 Bit Field Descriptions**

Bits	Field Name	Description
31-0	Reserved	Reserved

Teardown operation of an endpoint requires three operations. The teardown register in the CPPI DMA must be written, the corresponding endpoint bit in TEARDOWN of the USB module must be set, and the FlushFIFO bit in the Mentor USB controller Tx/RxCSR register must be set.

The following is the Transmit teardown procedure highlighting the steps required to be followed:

1. Set the TX\_TEARDOWN bit in the CPPI DMA TX channel n global configuration register (TXGCRn).
2. Set the appropriate TX\_TDOWN bit in the USBOTG controller's USB teardown register (TEARDOWN). Write Tx Endpoint Number to teardown to TEARDOWN[TX\_TDOWN] field.
3. Check if the teardown descriptor has been received on the teardown queue: The completion queue (see Queue Assignment table) is usually used as the Teardown Completion queue when the Teardown descriptor has been received, the descriptor address will be loaded onto CTRLD[Completion Queue #] register:
  - (a) If not, go to step 2
  - (b) If so, go to step 4
4. Set the appropriate TX\_TDOWN bit in the USBOTG controller's USB teardown register (TEARDOWN). Set the bit corresponding to the Channel Number within TEARDOWN[TX\_TDOWN] field.
5. Flush the TX FIFO in the Mentor OTG core: Set PERI\_TXCSR[FLUSHFIFO] for the corresponding Endpoint.
6. Re-enable the Tx DMA channel.
  - (a) Clear TXGCRn[TX\_TEARDOWN and TX\_ENABLE] bit.
  - (b) Set TXGCRn[TX\_ENABLE] bit.

### 16.3.9.3 Queue Manager

The queue manager (QM) is a hardware module that is responsible for accelerating management of the queues, i.e. queues are maintained within a queue manager module. Packets are added to a queue by writing the 32-bit descriptor address to a particular memory mapped location in the queue manager module. Packets are de-queued by reading the same location for that particular queue. A single queue manager exists within the device and handles all available 156 queues within the USB subsystem

Descriptors are queued onto a logical queue (pushed) by writing the descriptor pointer to the Queue N Register D. When the Queue N Register D is written, this kicks off the queue manager causing it to add the descriptor to the tail of queue.

The QM keeps track of the order of the descriptors pushed within a queue or the linking status of the descriptors. To accomplish this linking status, QM will first resolve the 32-bit descriptor pointer into a 16-bit index which is used for linking a queue pointer purposes. Once the address to index computation is performed, i.e., the physical index information is determined, the QM will link that descriptor onto the descriptor chain that is maintained for that logical queue by writing the linking information out to a linking RAM which is external to the queue manager. More on linking RAM discussion would follow in latter sections. The QM will also update the queue tail pointers appropriately. Since logical queues within the queue manager are maintained using linked lists, queues cannot become full and no check for fullness is required before queuing a packet descriptor.

#### 16.3.9.3.1 Queue Types

Several types of queues exist (a total of 156 queues) within the CPPI 4.1 DMA. Regardless of the type of queue, queues are used to hold pointers to Packet or Buffer Descriptors while they are being passed between the Host and / or any of the ports in the system. All queues are maintained within the single Queue Manager module.

The following types of Queues exist:

- Free descriptor queue (unassigned to specific endpoint but assigned to specific endpoint type; receive endpoints – can be used as a receive submit queue)
- Transmit submit queue
- Transmit completion (return) queue
- Receive completion (return) queue
- Teardown queue

Dedicated queues exist where one or more queues are assigned for the use of a single endpoint and non-dedicated queues exist where no specific queue assignment to an endpoint is required (but pertains to receive endpoints only). Transmit endpoints are not allowed to use free descriptor queues.

Dedicated queues exist for each specific endpoint use and non-dedicated queues exist that can be used by any/all receive endpoints. Three queues are reserved for each endpoint/port for transmit actions with two of the three queues being transmit submit queues while the remaining queue is used as a completion/return queue. For receive actions, the only dedicated queues are completion/return queues; one queue is assigned/reserved for each receive endpoint. 32 free descriptor queues that do not have dedicated endpoint-queue assignment exist and these queues are used to service any receive endpoint as receive submit queues.

[Table 16-27](#) displays queue-endpoint assignments.

**Table 16-27. Queue-Endpoint Assignments**

Queue Start Number	Queue Count	Queue-Endpoint Association
0	32	Free Descriptor Queues/Rx Submit Queues (USB0/1 Rx Endpoints)
32	2	USB0 Tx Endpoint 1
34	2	USB0 Tx Endpoint 2
36	2	USB0 Tx Endpoint 3
38	2	USB0 Tx Endpoint 4

**Table 16-27. Queue-Endpoint Assignments (continued)**

Queue Start Number	Queue Count	Queue-Endpoint Association
40	2	USB0 Tx Endpoint 5
42	2	USB0 Tx Endpoint 6

152	1	USB1 Rx Endpoint 12 completion queue
153	1	USB1 Rx Endpoint 13 completion queue
154	1	USB1 Rx Endpoint 14 completion queue
155	1	USB1 Rx Endpoint 15 completion queue

### 16.3.9.3.2 Free Descriptor Queue (Receive Submit Queue)

Receive endpoints/channels use queues, referred to as free descriptor queues, or receive submit queues, to forward completed receive packets to the host. The entries on the free descriptor queues have pre-attached empty buffers whose size and location are described in the original buffer information fields in the descriptor. The host is required to allocate both the descriptor and buffer and pre-link them prior to adding (submitting) a descriptor to one of the available free descriptor queue. The first 32 queues (queue 0 up to queue 31) are reserved for all 30 USB0/1 (endpoints 1 to 15 of each USB module) receive endpoints/channels to handle incoming packets to the device.

### 16.3.9.3.3 Transmit Submit Queue

Transmit ports use packet queues, referred to as transmit submit queues, to store the packets that are waiting to be transmitted. Each transmit endpoint has dedicated queues (2 queues per port) that are reserved exclusively for a use by a single endpoint. Multiple queues per port/channel are allocated to facilitate quality of service (QoS) for applications that require QoS. The first 30 queues, queue 32 up to queue 61, are allocated for USB0 transmit endpoints 1 to 15 with two queues per endpoint. queues 62 up to queue 91, are allocated for transmit USB1 endpoints 1 to 15.

### 16.3.9.3.4 Transmit Completion (Return) Queue

Transmit ports use packet queues, referred to as "transmit completion queues, to return packet descriptors to the host after packets have been transmitted. A single queue is reserved to be used by a single transmit endpoint. Application s/w needs to insure that the right set of queues is used to return the Descriptors after the completion of a packet transmission based on the endpoint number used. For USB0 transmit endpoints 1 to 15, queues 93–107 are reserved and assigned for use as a completion queue, respectively. Similarly for USB1 transmit endpoints 1 to 15, queues 125–139 are used as completion queues, respectively.

Transmit Completion Queues are also used to return packet Descriptors when performing a Transmit channel teardown operation.

### 16.3.9.3.5 Receive Completion (Return) Queue

Receive ports use packet queues, referred to as receive completion queues, to return packet descriptors to the port after packets have been received. A single queue is reserved to be used by a single receive endpoint. Application s/w needs to insure that the right set of queues is used to return the descriptors after the completion of a packet reception based on the endpoint number used. For USB0 receive endpoints 1 to 15 queues 122–136 are reserved/assigned for use as a receive completion queue respectively. Similarly for USB1 receive endpoints 1 to 15, queues 137–151 is used as completion queue respectively.

Receive channel teardown is not necessary for receive transactions and no channel teardown information nor resource is available

### 16.3.9.3.6 Diverting Queue Packets from one Queue to Another

The host can move the entire contents of one queue to another queue by writing the source queue number and the destination queue number to the Queue Diversion register. When diverting packets, the descriptors are pushed onto the tail of the destination queue.

## 16.3.9.4 Memory Regions and Linking RAM

In addition to allocating buffer for raw data and memory for Descriptors, the host is responsible for allocating additional memory for exclusive use of the CPPI DMA Queue Manager to be used as a scratch PAD RAM. The queue manager uses this memory to manage states of descriptors submitted within the submit queues. In other words, this memory needs not to be managed by the user software and firmware responsibility lies only for allocation/reserving a chunk of memory for the use of the queue manager. The allocated memory can be a single block of memory that is contiguous or two blocks of memory that are not contiguous. These two blocks of memory are referred to as a Linking RAM Regions and should not be confused with memory regions that are used to store descriptors. That is, the use of the term *region* should be used in the context of its use.

To accomplish the linking of submitted descriptors, the queue manager will first resolve the 32-bit descriptor pointer into a 16-bit index which is used for linking and queue pointer purposes. Once the physical index information is determined, the queue manager will link that descriptor onto the descriptor chain that is maintained for that logical queue by writing the linking information out to a linking RAM which is external to the queue manager. The queue manager will also update the queue tail pointer appropriately. Since logical queues within the queue manager are maintained using linked lists, queues cannot become full and no check for fullness is required before queuing a packet descriptor.

The actual physical size of the Linking RAM region(s) to be allocated depends on the total number of descriptors defined within all memory regions. A minimum of four bytes of memory needs to be allocated for each Descriptor defined within all 16 memory regions.

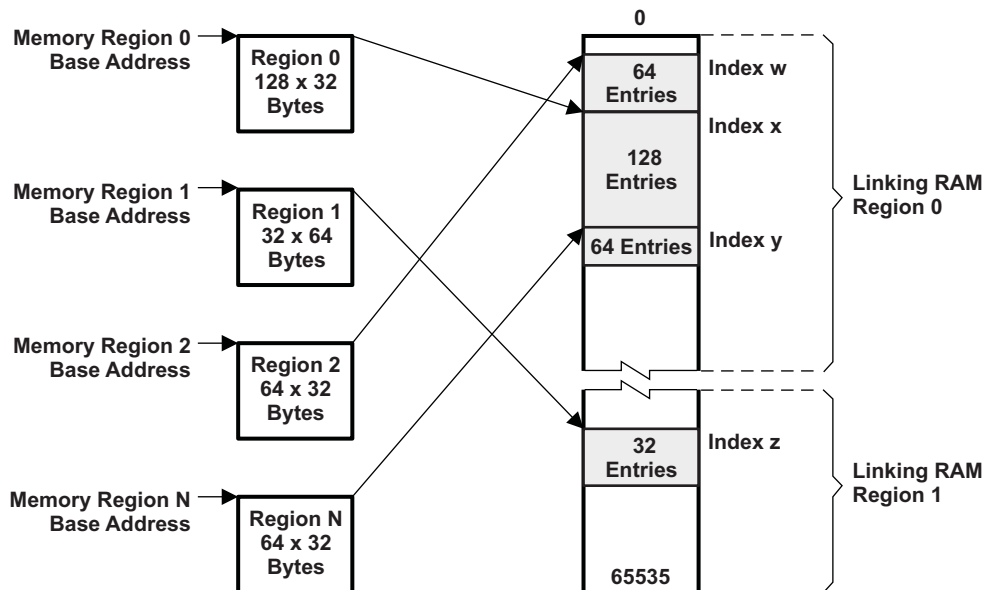

The queue manager has the capability of managing up to 16 memory regions. These memory regions are used to store descriptors of variable sizes. The total number of descriptors that can be managed by the queue manager should not exceed 64K. Each memory region has descriptors of one configurable size, that is, descriptors with different sizes cannot be housed within a single memory region. These 64K descriptors are referenced internally in the queue manager by a 16-bit quantity index.

The information about the Linking RAM regions and the size that are allocated is communicated to the CPPI DMA via three registers dedicated for this purpose. Two of the three registers are used to store the 32-bit aligned start addresses of the Linking RAM regions. The remaining one register is used to store the size of the first Linking RAM. The linking RAM size value stored here is the number of descriptors that is to be managed by the queue manager within that region not the physical size of the buffer, which is four times the number of descriptors.

Note that application is not required to use both linking RAM regions, if the size of the Linking RAM for the first region is large enough to accommodate all descriptors defined. No linking RAM size register for linking RAM region 2 exists. The size of the second linking RAM, when used, is indirectly computed from the total number of descriptors defined less the number of descriptors managed by the first linking RAM

Figure 16-16 displays the relationship between several memory regions and linking RAM.

**Figure 16-16. Relationship Between Memory Regions and Linking RAM**

### 16.3.9.5 Zero Length Packets

A special case is the handling of null packets with the CPPI 4.1 compliant DMA controller. Upon receiving a zero length USB packet, the XFER DMA will send a data block to the DMA controller with byte count of zero and the zero byte packet bit of INFO Word 2 set. The DMA controller will then perform normal End of Packet termination of the packet, without transferring data.

If a zero-length USB packet is received, the XDMA will send the CDMA a data block with a byte count of 0 and this bit set. The CDMA will then perform normal EOP termination of the packet without transferring data. For transmit, if a packet has this bit set, the XDMA will ignore the CPPI packet size and send a zero-length packet to the USB controller.

### 16.3.9.6 CPPI DMA Scheduler

The CPPI DMA scheduler is responsible for controlling the rate and order between the different Tx and Rx threads/transfers that are provided in the CPPI DMA controller. The scheduler table RAM exists within the scheduler.

The DMA controller maintains state information for each of the channels which allows packet segmentation and reassembly operations to be time division multiplexed between channels in order to share the underlying DMA hardware. A DMA scheduler is used to control the ordering and rate at which this multiplexing occurs.

#### 16.3.9.6.1 CPPI DMA Scheduler Operation

Once the scheduler is enabled it will begin processing the entries in the table. When appropriate the scheduler will pass credits to the DMA controller to perform a Tx or Rx operation. The operation of the DMA controller is as follows:

1. After the DMA scheduler is enabled it begins with the table index set to 0.
2. The scheduler reads the entry pointed to by the index and checks to see if the channel in question is currently in a state where a DMA operation can be accepted.
  - (a) The DMA channel must be enabled AND
  - (b) The CPPI FIFO that the channel talks to has free space on TX (FIFO full signal is not asserted) or a valid block on Rx (FIFO empty signal is not asserted)
3. If the DMA channel is capable of processing a credit to transfer a block, the DMA scheduler will issue that credit via the DMA scheduling interface which is a point to point connection between the DMA Scheduler and the DMA Controller.
  - (a) The DMA controller may not be ready to accept the credit immediately and is provided a sched\_ready signal which is used to stall the scheduler until it can accept the credit. The DMA controller only asserts the sched\_ready signal when it is in the IDLE state.
  - (b) Once a credit has been accepted (indicated by sched\_req and sched\_ready both asserted), the scheduler will increment the index to the next entry and will start again at step 2.
4. If the channel in question is not currently capable of processing a credit, the scheduler will increment the index in the scheduler table to the next entry and will start at step 2.
5. Note that when the scheduler attempts to increment its index, to the value programmed in the table size register, the index will be reset to 0.

##### 16.3.9.6.1.1 CPPI DMA Scheduler Initialization

Before the scheduler can be used, the host is required to initialize and enable the block. This initialization is performed as follows:

1. The Host initializes entries within an internal memory array in the scheduler. This array contains up to 256 entries (4 entries per table word  $n$  where  $n=0-63$ ) and each entry consists of a DMA channel number and a bit indicating if this is a Tx or Rx opportunity. These entries represent both the order and frequency that various Tx and Rx channels will be processed. A table size of 256 entries allows channel bandwidth to be allocated with a maximum precision of 1/256th of the total DMA bandwidth. The more entries that are present for a given channel, the bigger the slice of the bandwidth that channel will be given. Larger tables can be accommodated to allow for more precision. This array can only be written by the Host, it cannot be read.
2. If the application does not need to use the entire 256 entries, firmware can initialize the portion of the 256 entries and indicate the size of the entries used by writing onto an internal register in the scheduler which sets the actual size of the array (it can be less than 256 entries).
3. The host writes an internal register bit to enable the scheduler. The scheduler is not required to be disabled in order to change the scheduler array contents.

### 16.3.9.6.1.2 CPPI DMA Scheduler Programming Examples

Consider a three endpoints use on a system with the following configurations: EP1-Tx, EP2-Rx, and EP2-Tx. Two assumptions are considered:

**Case 1:** Assume that you would like to service each enabled endpoints (EP1-Tx, EP2-Rx, and EP2-Tx) with equal priority.

The scheduler handles the rate at which an endpoint is serviced by the number of credits programmed (entries) for that particular endpoint within the scheduler Table Words. The scheduler has up to 256 credits that it can grant and for this example the user can configure the number of entries/credits to be anywhere from 3 to 256 with a set of 3 entries.

However, the optimum and direct programming for this scenario would be programming only the first three entries of the scheduler via scheduler Table WORD[0]. Since this case expects the Scheduler to use only the first three entries, you communicate that by programming DMA\_SCHED\_CTRL.LAST\_ENTRY with 2 (that is, 3 -1). The Enabled Endpoint numbers and the data transfer direction is then communicated by programming the first three entries of WORD[0] (ENTRY0\_CHANNEL = 1: ENTRY0\_RXTX = 0; ENTRY1\_CHANNEL = 2: ENTRY1\_RXTX = 1; ENTRY2\_CHANNEL = 2: ENTRY2\_RXTX = 0). With this programming, the Scheduler will only service the first three entries in a round-robin fashion, checking each credited endpoint for transfer one after the other, and servicing the endpoint that has data to transfer.

**Case 2:** Enabled endpoint EP1-Tx is serviced at twice the rate as the other enabled endpoints (EP2-Rx and EP2-Tx).

The number of entries/credit that has to be awarded to EP1-Tx has to be twice as much of the others. Four entries/credits would suffice to satisfy our requirement with two credits for EP1-Tx, one credit for EP2-Rx, and one credit for EP2-Tx. This requirement is satisfied by allocating any two of the four entries to EP1-Tx endpoint. Again for this example, scheduler Table WORD[0] would suffice since it can handle the first 4 entries. Even though several scenarios exist to programming the order of service for this case, one scenario would be to allow servicing EP1-Tx to back-to-back followed by the other enabled endpoints. Program DMA\_SCHED\_CTRL.LAST\_ENTRY with 3 (that is, 4 -1). Program WORD[0] (ENTRY0\_CHANNEL = 1: ENTRY0\_RXTX = 0; ENTRY1\_CHANNEL = 1: ENTRY1\_RXTX = 0; ENTRY2\_CHANNEL = 2: ENTRY2\_RXTX = 1; ENTRY3\_CHANNEL = 2: ENTRY3\_RXTX = 0).

### 16.3.9.7 CPPI DMA State Registers

The port must store and maintain state information for each transmit and receive port/channel. The state information is referred to as the Tx DMA State and Rx DMA State.

#### 16.3.9.7.1 Transmit DMA State Registers

The Tx DMA State is a combination of control fields and protocol specific port scratchpad space used to manipulate data structures and transmit packets. Each transmit channel has two queues. Each queue has a one head descriptor pointer and one completion pointer. There are thirty Tx DMA State registers; one for each port/channel.

The following information is stored in the Tx DMA State:

- Tx Queue Head Descriptor Pointer(s)
- Tx Completion Pointer(s)
- Protocol specific control/status (port scratchpad)

#### 16.3.9.7.2 Receive DMA State Registers

The Rx DMA State is a combination of control fields and protocol specific port scratchpad space used to manipulate data structures in order to receive packets. Each receive channel has only one queue. Each channel queue has one head descriptor pointer and one completion pointer. There are thirty Rx DMA State registers; one for each port/channel.

The following information is stored in the Rx DMA State:

- Rx Queue Head Descriptor Pointer
- Rx Queue Completion Pointer

- Rx Buffer Offset

### 16.3.9.8 CPPI DMA Protocols Supported

Four different type of DMA transfers are supported by the CPPI 4.1 DMA; Transparent, RNDIS, Generic RNDIS, and Linux CDC. The following sections will outline the details on these DMA transfer types.

#### 16.3.9.8.1 Transparent DMA Transfer

Transparent Mode DMA operation is the default DMA mode where DMA interrupt is generated whenever a DMA packet is transferred. In the transparent mode, DMA packet size cannot be greater than USB MaxPktSize for the endpoint. This transfer type is ideal for transfer (not packet) sizes that are less than a max packet size.

##### 16.3.9.8.1.1 Transparent DMA Transfer Setup

The following will configure all 30 ports/channels for Transparent DMA Transfer type.

Make sure that RNDIS Mode is disabled globally. This allows the application to configure the CPPI DMA protocol in use to be configured per endpoint need. To disable RNDIS operation, clear RNDIS bit in the USB Control Registers corresponding to the USB Module (default setting), i.e., CTRL0[RNDIS]=0 and CTRL1[RNDIS]=0.

Configure the USB0/1 Tx/Rx DMA Mode Registers (USB0/1 TX(RX)MODE0/1) for the Endpoint field in use is programmed for Transparent Mode, i.e., TXMODE0/1[TXn\_MODE] = 00b and RXMODE0/1[RXn\_MODE] = 00b.

#### 16.3.9.8.2 RNDIS DMA Transfer

RNDIS mode DMA is used for large transfers (i.e., total data size to be transferred is greater than USB MaxPktSize where the MzxPktSize is a multiple of 64 bytes) that requires multiple USB packets. This is accomplished by breaking the larger packet into smaller packets, where each packet size being USB MaxPktSize except the last packet where its size is less than USB MaxPktSize, including zero bytes. This implies that multiple USB packets of MaxPktSize will be received and transferred together as a single large DMA transfer and the DMA interrupt is generated only at the end of the complete reception of DMA transfer. The protocol defines the end of the complete transfer by receiving a short USB packet (smaller than USB MaxPktSize as mentioned in USB specification 2.0). If the DMA packet size is an exact multiple of USB MaxPktSize, the DMA controller waits for a zero byte packet at the end of complete transfer to signify the completion of the transfer.

**NOTE:** RNDIS Mode DMA is supported only when USB MaxPktSize is an integral multiple of 64 bytes.

##### 16.3.9.8.2.1 RNDIS DMA Transfer Setup

If all endpoints in use are desired to operate in RNDIS mode, it is only suffix to configure RNDIS DMA operation in RNDIS mode at the global level and application can ignore individual endpoint DMA mode configuration. This is achieved by programming CTRLR0/1[RNDIS] with a '1.'

However if DMA mode is required to be configured at the endpoint level, it is required to disable the use of RNDIS at the global level, this is achieved by clearing RNDIS bit field (CTRLR0/1[RNDIS]=0), since global configuration over-rides endpoint configuration.

To configure RNDIS DMA mode use, configure the field that correspond to the USB module endpoint using the corresponding USB0/1 TX(RX) Mode Register, i.e., TXMODE0/1[TXn\_MODE] = 01b and RXMODE0/1[RXn\_MODE] = 01b

#### 16.3.9.8.3 Generic RNDIS DMA Transfer

Generic RNDIS DMA transfer mode is identical to the normal RNDIS mode in nearly all respects, except for the exception case where the last packet of the transfer can either be a short packet or the MaxPktSize. When the last packet size is equal to the MaxPktSize then no additional zero-byte packet is sent when using Generic RNDIS transfer. Generic RNDIS transfer makes use of a USB0/1 GENERIC RNDIS EPn Size register (there exists a register for each endpoint) that must be programmed with the

transfer size (in bytes) of the transfer for the USB Module (USB0 or USB1) prior to posting a transfer transaction. If the transfer size is an integer multiple of USB MaxPktSize then no additional zero-byte packet is sent when using Generic RNDIS transfer. However, if the a short packet has been sent prior to programmed size count, the transfer would end in a similar fashion an RDIS transfer would behave. For example, if the USB MaxPktSize (Tx/RxMaxP) is programmed with a value of 64, the Generic RNDIS EP Size register for that endpoint must be programmed with a value that is an integer multiple of 64 (for example, 64, 128, 192, 256, etc.) for it behave differently than RNDIS transfer. In other words, when using Generic RNDIS mode and the DMA is tasked to transfer data transfer size that is less or equal the size value programmed within the USB0/1 GENERIC RNDIS EPn Size register.

This means that Generic RNDIS mode will perform data transfer in the same manner as RNDIS mode, closing the CPPI packet if a USB packet with a size less than the USB MaxPktSize size value is received. Otherwise, the packet will be closed when the value in the Generic RNDIS EP Size register is reached.

Using USB0/1 GENERIC RNDIS EPn Size register, a packet of up to 64K bytes (65536 bytes) can be transferred. This is to allow the host software to program the USB module to transfer data that is an exact multiple of the USB MaxPktSize (Tx/RxMaxP programmed value) without having to send an additional short packet to terminate.

**NOTE:** As in RNDIS mode, the USB max packet size (Tx/RxMaxp programmed value) of any Generic RNDIS mode enabled endpoints must be a multiple of 64 bytes. Generic RNDIS acceleration should not be enabled for endpoints where the max packet size is not a multiple of 64 bytes. Only transparent mode should be used for such endpoints.

#### 16.3.9.8.3.1 Generic RNDIS DMA Transfer Setup

Disable the use of RNDIS at the global level, this is achieved by clearing RNDIS bit field (CTRLR0/1[RNDIS]=0), since global configuration over-rides endpoint configuration.

Configure the field that correspond to the USB module endpoint using the corresponding USB0/1 TX(RX) Mode Register, i.e., TXMODE0/1[TXn\_MODE] = 11b and RXMODE0/1[RXn\_MODE] = 11b.

#### 16.3.9.8.4 Linux CDC DMA Transfer

Linux CDC DMA transfer mode acts in the same manner as RNDIS packets, except for the case where the last data matches the max USB packet size requiring additional zero-byte packet transfer in RNDIS mode and this is not the case for Linux CDC. If the last data packet of a transfer is a short packet where the data size is greater than zero and less the USB MaxPktSize, then the behavior of the Linux CDC DMA transfer type is identical with the RNDIS DMA transfer type. The only exception is when the short packet length terminating the transfer is a Null Packet. In this case, instead of transferring the Null Packet, it will transfer a data packet of size 1 byte with the data value of 00h.

In transmit operation, if an endpoint is configured or CDC Linux mode, upon receiving a Null Packet from the CPPI DMA, the XFER DMA will then generate a packet containing 1 byte of data, whose value is 00h, indicating the end of the transfer. During receive operation, the XFER DMA will recognize the one byte zero packet as a termination of the data transfer, and sends a block of data with the EOP indicator set and a byte count of one to the CPPI DMA controller. The CPPI DMA realizing the end of the transfer termination will not update/increase the packet size count of the Host Packet Descriptor.

#### 16.3.9.8.4.1 Linux CDC DMA Transfer Setup

Disable the use of RNDIS at the global level, this is achieved by clearing RNDIS bit field (CTRLR0/1[RNDIS]=0), since global configuration over-rides endpoint configuration.

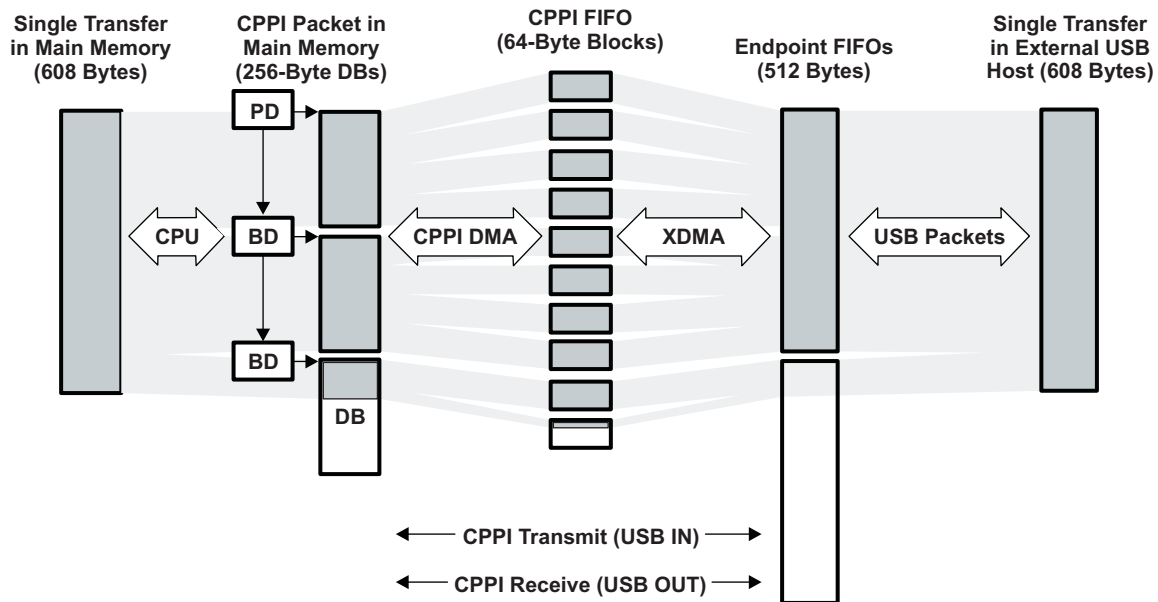

Configure the field that correspond to the USB module endpoint using the corresponding USB0/1 TX(RX) Mode Register, i.e., TXMODE0/1[TXn\_MODE] = 10b and RXMODE0/1[RXn\_MODE] = 10b.

#### 16.3.9.9 USB Data Flow Using DMA

The necessary steps required to perform a USB data transfer using the CPPI 4.1 DMA is expressed using an example for both transmit and receive cases. Assume USB0 is ready to perform a USB data transfer of size 608 bytes (see [Figure 16-17](#)).

The 608 bytes data to be transferred is described using three descriptors. Since each data buffer defined within a single descriptor has a size of 256 bytes, a 608 bytes data buffer would require three descriptors.

**Figure 16-17. High-level Transmit and Receive Data Transfer Example**

**Example assumptions:**

- The CPPI data buffers are 256 bytes in length.
- USB0 module is to be used to perform this transfer. Note that the steps required is similar for USB1 use.
- The USB0 endpoint 1 Tx and Rx endpoint 1 size are programmed to handle max USB packet size of 512 bytes.
- A single transfer length is 608 bytes.
- The SOP offset is 0.

The above translates to the following multi-descriptor setup:

**Transmit Case**

Transmit setup is as follows:

- One packet descriptor with packet length (this is NOT data buffer length, the term packet used here is to mean a transfer length not USB packet) field of 608 bytes and a Data Buffer of size 256 Bytes linked to the 1st host buffer descriptor.
- Two buffer descriptors with first buffer descriptor (this is the one linked to the packet descriptor) defining the second data buffer size of 256 Bytes which in turn is linked to the next (second) buffer descriptor.
- Second buffer descriptor with a data buffer size of 96 bytes (can be greater, the packet descriptor contain the size of the packet) linked to no other descriptor (NULL).

**Receive Case**

For this example since each data buffer size is 256 bytes, we would require a minimum of three descriptors that would define data buffer size of 608 bytes. The receive setup is as follows:

- Two buffer descriptors with 256 bytes of data buffer size
- One buffer descriptor with 96 bytes (can be greater) of data buffer size

Within the rest of this section, the following nomenclature is used:

**BD** — Buffer Descriptor or Host Buffer Descriptor

**DB** — Data Buffer Size of 256 Bytes

**PBD** — Pointer to Host Buffer Descriptor

**PD** — Host Packet Descriptor

**PPD** — Pointer to Host Packet Descriptor

**TXSQ** — Transmit Queue or Transmit Submit Queue (for USB0 EP1, use Queues 32 or 33, for USB1 EP1 use Queues 62 or 63)

**TXCQ** — Transmit Completion Queue or Transmit Return Queue (for USB0 Tx EP1, use Queue 93, and for USB1 Tx EP1 use Queue 125)

**RXCQ** — Receive Completion Queue or Receive Return Queue (for USB0 Rx EP1, use Queue 109, for USB1 Rx EP1 use Queue 141)

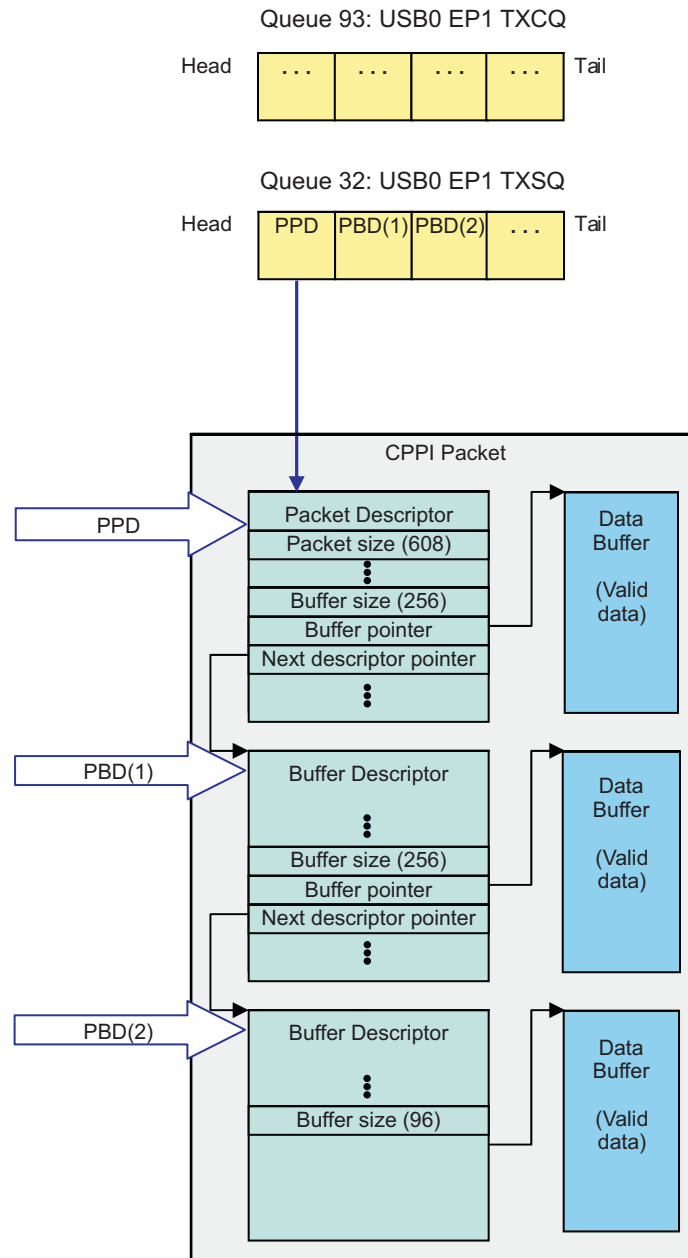

**RXSQ** — Receive Free/Buffer Descriptor Queue or Receive Submit Queue. (For USB0 Rx EP1 Queue 0 is used and for USB1 Rx EP1 Queue 16 should be used)

#### **16.3.9.9.1 Transmit USB Data Flow Using DMA**

The transmit descriptors and queue status configuration prior to the transfer taking place is shown in [Figure 16-18](#).

**Figure 16-18. Transmit Descriptors and Queue Status Configuration**

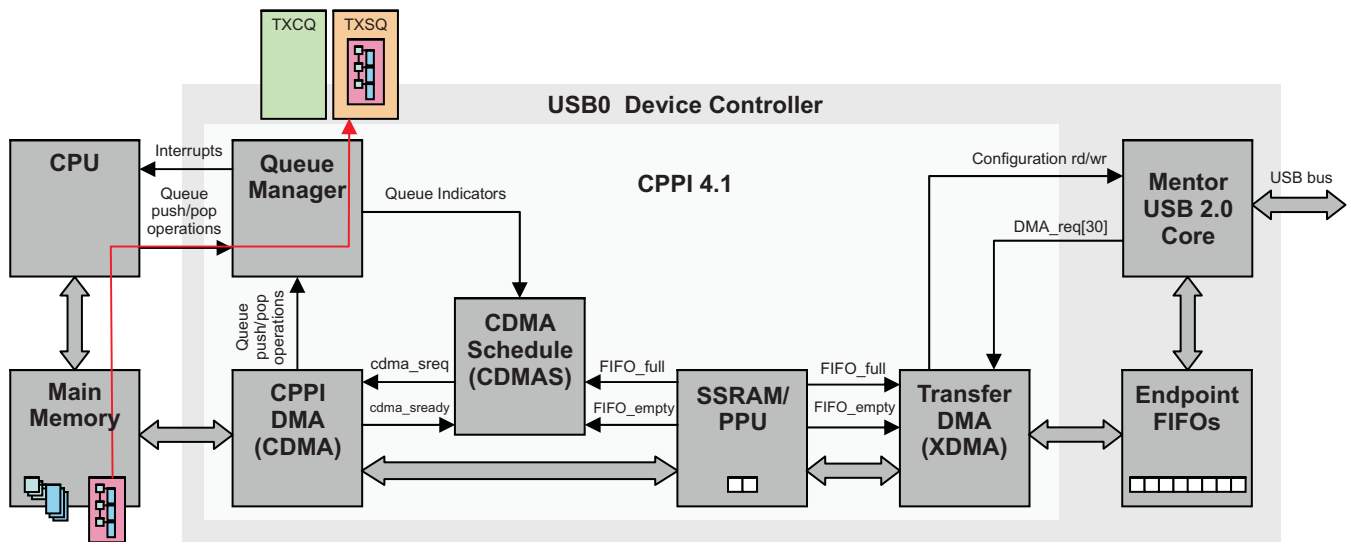

**16.3.9.9.1.1 Transmit Initialization (Step 1)**

The CPU performs the following steps for transmit initialization:

1. Initializes Memory Region 0 base address and Memory Region 0 size, Link RAM0 Base address, Link RAM0 data size, and Link RAM1 Base address.
2. Creates PD, BDs, and DBs in main memory and link as indicated in [Figure 16-19](#).
3. Initializes and configures the Queue Manager, Channel Setup, DMA Scheduler, and Mentor USB 2.0 Core.
4. Adds (pushes) the PPD and the two PBDs to the TXSQ by writing the Packet Descriptor address to the TXSQ CTRL D Register.

[Figure 16-19](#) captures the BD/DB pair in main memory and later submitted within the TXSQ.

**Figure 16-19. Transmit USB Data Flow Example (Initialization)**

#### 16.3.9.9.1.2 CDMA and XDMA Transfer Packet Data Into Endpoint FIFO (Step 2)

The steps for CDMA and XDMA to transfer packet data into endpoint FIFO are as follows:

1. The Queue Manager informs the CDMAS that the TXSQ is not empty.
2. CDMAS checks that the CPPI FIFO FIFO\_full is not asserted, then issues a credit to the CDMA.
3. CDMA reads the Packet Descriptor pointer (PPD) and descriptor size hint from the queue manager
4. For each 64-byte block of data in the packet data payload (note that packet refers here to CPPI packet which is not the same as USB packet and it means to refer to data transfer size):
  - (a) The CDMA transfers a max burst of 64-byte block (OCP burst) from the data to be transferred in main memory to the CPPI FIFO
  - (b) The XDMA sees FIFO\_empty not asserted and transfers 64-byte block from CPPI FIFO to Endpoint FIFO.
  - (c) The CDMA performs the above two steps ('a' and 'b') three more times since the data size of the HPD is 256 bytes.
5. The CDMA reads the first buffer descriptor pointer (PBD).
6. For each 64-byte block of data in the packet data payload:
  - (a) The CDMA transfers a max burst of 64-byte block from the data to be transferred in main memory to the CPPI FIFO.
  - (b) The XDMA sees FIFO\_empty not asserted and transfers 64-byte block from CPPI FIFO to Endpoint FIFO.
  - (c) The CDMA performs the above two steps ('a' and 'b') two more times since data size of the HBD is 256 bytes.
7. The CDMA reads the second Buffer Descriptor pointer (PBD)
8. For each 64-byte block of data in the packet data payload:
  - (a) The CDMA transfers a max burst of 64-byte block from the data to be transferred in main memory to the CPPI FIFO.
  - (b) The XDMA sees FIFO\_empty not asserted and transfers 64-byte block from CPPI FIFO to Endpoint FIFO.
  - (c) The CDMA transfers the last remaining 32-byte from the data to be transferred in main memory to the CPPI FIFO.
  - (d) The XDMA sees FIFO\_empty not asserted and transfers 32-byte block from CPPI FIFO to Endpoint FIFO.

#### **16.3.9.9.1.3 USB 2.0 Core Transmits USB Packets for Tx (Step 3)**

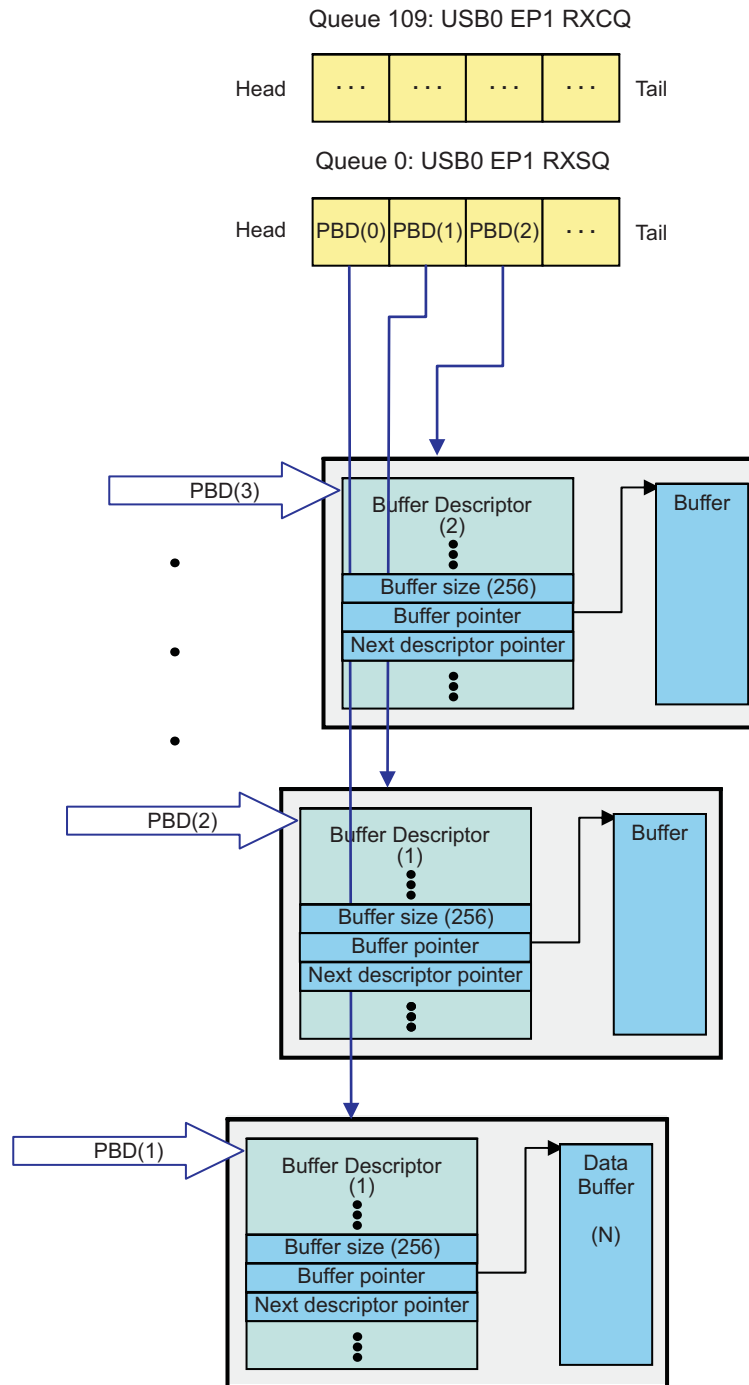

1. Once the XDMA has transferred enough 64-byte blocks of burst of data from the CPPI FIFO to fill the Endpoint FIFO (accumulated 512 bytes), it signals the Mentor USB 2.0 Core that a TX packet is ready (sets the endpoint's TxPktRdy bit).
2. The USB 2.0 Core will transmit the packet from the Endpoint FIFO out on the USB BUS when it receives a corresponding IN request from the attached USB Host.
3. After the USB packet is transferred, the USB 2.0 Core issues a TX DMA\_req to the XDMA.
4. This process is repeated until (the above steps '1', '2', and '3') the entire packet has been transmitted. The XDMA will also generate the required termination packet depending on the termination mode configured for the endpoint.

#### **16.3.9.9.1.4 Return Packet to Completion Queue and Interrupt CPU for Tx (Step 4)**

1. After all data for the packet has been transmitted (as specified by the packet size field), the CDMA will write the pointer of the Packet Descriptor only to the TX Completion Queue specified in the return queue manager / queue number fields of the packet descriptor.
2. The Queue Manager then indicates the status of the TXSQ (empty) to the CDMAS and the TXCQ to the CPU via an interrupt.

#### **16.3.9.9.2 Receive USB Data Flow Using DMA**

The receive buffer descriptors and queue status configuration prior to the transfer taking place is shown in [Figure 16-20](#).

**Figure 16-20. Receive Buffer Descriptors and Queue Status Configuration**

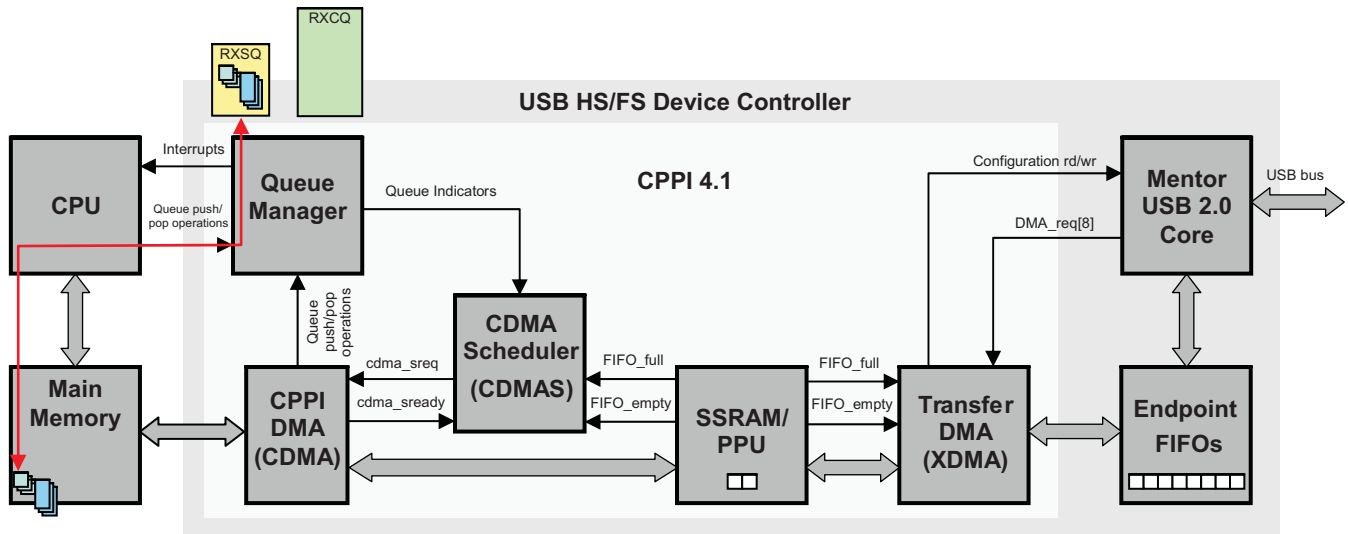

#### 16.3.9.9.2.1 Receive Initialization (Step 1)

1. The CPU initializes Queue Manager with the Memory Region 0 base address and Memory Region 0 size, Link RAM0 Base address, Link RAM0 data size, and Link RAM1 Base address.
2. The CPU creates BDs, and DBs in main memory and link them creating a BD and DB pairs.
3. CPU then initializes the RXCQ queue and configures the Queue Manager, Channel Setup, DMA Scheduler, and USB 2.0 Core.
4. It then adds (pushes) the address of the addresses/pointers of three Buffer Descriptors (PBDs) into the

RXSQ by writing onto CTRL D register.

Figure 16-21 displays receive operation Initialization.

Figure 16-21. Receive USB Data Flow Example (Initialization)

**16.3.9.9.2 USB 2.0 Core Receives a Packet, XDMA Starts Data Transfer for Receive (Step 2)**

1. The USB 2.0 Core receives a USB packet from the USB Host and stores it in the Endpoint FIFO.
2. It then asserts a DMA\_req to the XDMA informing it that data is available in the Endpoint FIFO.
3. The XDMA verifies the corresponding CPPI FIFO is not full via the FIFO\_full signal, then starts transferring 64-byte data blocks (burst) from the Endpoint FIFO into the CPPI FIFO.

**16.3.9.9.3 CDMA Transfers Data from SSRAM / PPU to Main Memory for Receive (Step 3)**

1. The CDMAS see FIFO\_empty de-asserted (there is RX data in the FIFO) and issues a transaction credit to the CDMA.
2. The CDMA begins packet reception by fetching the first PBD from the Queue Manager using the Free Descriptor / Buffer Queue 0 (Rx Submit Queue) index that was initialized in the RX port DMA state for that channel.
3. The CDMA will then begin writing the 64-byte block of packet data into this DB.
4. The CDMA will continue filling the buffer with additional 64-byte blocks of data from the CPPI FIFO and will fetch additional PBD as needed using the Free Descriptor / Buffer Queue 1, 2, and 3 indexes for the 2nd, 3rd, and remaining buffers in the packet. After each buffer is filled, the CDMA writes the buffer descriptor to main memory.

**16.3.9.9.4 CDMA Completes the Packet Transfer for Receive (Step 4)**

1. After the entire packet has been received, the CDMA writes the packet descriptor to main memory.
2. The CDMA then writes the packet descriptor to the RXCQ specified in the Queue Manager / Queue Number fields in the RX Global Configuration Register.
3. The Queue Manager then indicates the status of the RXCQ to the CPU via an interrupt.
4. The CPU can then process the received packet by popping the received packet information from the RXCQ and accessing the packet's data from main memory.

### 16.3.10 USB 2.0 Test Modes

The USB2.0 controller supports the four USB 2.0 test modes (Test\_SE0\_NAK, Test\_J, Test\_K, and Test\_Packet) defined for high-speed functions. It also supports an additional “FIFO access” test mode that can be used to test the operation of the CPU interface, the DMA controller and the RAM block.

The test modes are entered by writing to the TESTMODE register. A test mode is usually requested by the host sending a SET\_FEATURE request to Endpoint 0. When the software receives the request, it should wait until the Endpoint 0 transfer has completed (when it receives the Endpoint 0 interrupt indicating the status phase has completed) then write to the TESTMODE register.

**Note:** These test modes have no purpose in normal operation.

#### 16.3.10.1 TEST\_SE0\_NAK

To enter the Test\_SE0\_NAK test mode, the software should set the TEST\_SE0\_NAK bit in the TESTMODE register to 1. The USB controller will then go into a mode in which it responds to any valid IN token with a NAK.

#### 16.3.10.2 TEST\_J

To enter the Test\_J test mode, the software should set the TEST\_J bit in the TESTMODE register to 1. The USB controller will then go into a mode in which it transmits a continuous J on the bus.

#### 16.3.10.3 TEST\_K

To enter the Test\_K test mode, the software should set the TEST\_K bit in the TESTMODE register to 1. The USB controller will then go into a mode in which it transmits a continuous K on the bus.

#### 16.3.10.4 TEST\_PACKET

To execute the Test\_Packet, the software should:

1. Start a session (if the core is being used in Host mode).
2. Write the standard test packet (shown below) to the Endpoint 0 FIFO.
3. Write 8h to the TESTMODE register (TEST\_PACKET = 1) to enter Test\_Packet test mode.
4. Set the TxPktRdy bit in the HOST/PERI\_CSR0 register (bit 1).

The 53 byte test packet to load is as follows (all bytes in hex). The test packet only has to be loaded once; the USB controller will keep re-sending the test packet without any further intervention from the software.

[Table 16-28](#) displays the 53 Bytes test packet content.

**Table 16-28. 53 Bytes Test Packet Content**

0	0	0	0	0	0	0	0
0	AA	AA	AA	AA	AA	AA	AA
AA	EE	EE	EE	EE	EE	EE	EE
EE	FE	FF	FF	FF	FF	FF	FF
FF	FF	FF	FF	FF	7F	BF	DF
EF	F7	FB	FD	FC	7E	BF	DF
EF	F7	FB	FD	7E			

This data sequence is defined in Universal Serial Bus Specification Revision 2.0, Section 7.1.20. The USB controller will add the DATA0 PID to the head of the data sequence and the CRC to the end.

### 16.3.10.5 FIFO\_ACCESS

The FIFO Access test mode allows you to test the operation of CPU Interface, the DMA controller (if configured), and the RAM block by loading a packet of up to 64 bytes into the Endpoint 0 FIFO and then reading it back out again. Endpoint 0 is used because it is a bidirectional endpoint that uses the same area of RAM for its Tx and Rx FIFOs.

**NOTE:** The core does not need to be connected to the USB bus to run this test. If it is connected, then no session should be in progress when the test is run.

The test procedure is as follows:

1. Load a packet of up to 64 bytes into the Endpoint 0 Tx FIFO.
2. Set HOST/PERI\_CSR0[TXPKTRDY].
3. Write 40h to the TESTMODE register (FIFO\_ACCESS = 1).
4. Unload the packet from the Endpoint Rx FIFO, again.
5. Set HOST/PERI\_CSR0[SERVICEDRXPKTRDY].

Writing 40h to the TESTMODE register causes the following sequence of events:

The Endpoint 0 CPU pointer (that records the number of bytes to be transmitted) is copied to the Endpoint 0 USB pointer (that records the number of bytes received).

1. The Endpoint 0 CPU pointer is reset.
2. HOST/PERI\_CSR0[TXPKTRDY] is cleared.
3. HOST/PERI\_CSR0[RXPKTRDY] is set.
4. An Endpoint 0 interrupt is generated (if enabled).

The effect of these steps is to make the Endpoint 0 controller act as if the packet loaded into the Tx FIFO has flushed and the same packet received over the USB. The data that was loaded in the Tx FIFO can now be read out of the Rx FIFO.

### 16.3.10.6 FORCE\_HOST

The Force Host test mode enables you to instruct the core to operate in Host mode, regardless of whether it is actually connected to any peripheral; that is, the state of the CID input and the LINESTATE and HOSTDISCON signals are ignored. (While in this mode, the state of the HOSTDISCON signal can be read from the BDEVICE bit in the device control register (DEVCTL)).

This mode, which is selected by writing 80h to the TESTMODE register (FORCE\_HOST = 1), allows implementation of the USB Test\_Force\_Enable (USB 2.0 Specification Section 7.1.20). It can also be used for debugging PHY problems in hardware.

While the FORCE\_HOST bit remains set, the core enters the Host mode when the SESSION bit in DEVCTL is set to 1 and remains in the Host mode until the SESSION bit is cleared to 0 even if a connected device is disconnected during the session. The operating speed while in this mode is determined by the FORCE\_HS and FORCE\_FS bits in the TESTMODE register.

## 16.4 Supported Use Cases

The USB Subsystem supports two independent USB Modules where each USB module can operate as a host or peripheral. When operating as a host, it is capable of interfacing to a single target/peripheral directly or to multiple targets via hub at low-, full-, or high-speed. When operating as a peripheral, it is capable of interfacing to a host at a full- or high-speed.

## 16.5 USB Registers

### 16.5.1 USBSS Registers

Table 16-29 lists the memory-mapped registers for the USBSS. All register offset addresses not listed in Table 16-29 should be considered as reserved locations and the register contents should not be modified.

**Table 16-29. USBSS REGISTERS**

Offset	Acronym	Register Name	Section
0h	REVREG		<a href="#">Section 16.5.1.1</a>
10h	SYSCONFIG		<a href="#">Section 16.5.1.2</a>
24h	IRQSTATRAW		<a href="#">Section 16.5.1.3</a>

### 16.5.1.1 REVREG Register (offset = 0h) [reset = 4EA20800h]

REVREG is shown in [Figure 16-22](#) and described in [Table 16-30](#).

**Figure 16-22. REVREG Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-30. REVREG Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-30	SCHEME	R	1h	Used to distinguish between legacy interface scheme and current. 0 = Legacy 1 = Current
27-16	FUNC	R	EA2h	Function indicates a software compatible module family.
15-11	R_RTL	R	1h	RTL revision. Will vary depending on release.
10-8	X_MAJOR	R	0h	Major revision.
7-6	CUSTOM	R	0h	Custom revision
5-0	Y_MINOR	R	0h	Minor revision. USBSS Revision Register

### 16.5.1.2 SYSCONFIG Register (offset = 10h) [reset = 28h]

SYSCONFIG is shown in [Figure 16-23](#) and described in [Table 16-31](#).

**Figure 16-23. SYSCONFIG Register**

31	30	29	28	27	26	25	24

10	TX_PKT_CMP_1	R/W	0h	Interrupt enable for USB1 Tx CPPI DMA packet completion status
9	RX_PKT_CMP_0	R/W	0h	Interrupt enable for USB0 Rx CPPI DMA packet completion status
8	TX_PKT_CMP_0	R/W	0h	Interrupt enable for USB0 Tx CPPI DMA packet completion status
2	PD_CMP_FLAG	R/W	0h	Interrupt enable when the packet is completed, the differ bits is set, and the Packet Descriptor is pushed into the queue manager
1	RX_MOP_STARVATION	R/W	0h	Interrupt enable when queue manager cannot allocate an Rx buffer in the middle of a packet.
0	RX_SOP_STARVATION	R/W	0h	Interrupt enable when queue manager cannot allocate an Rx buffer at the start of a packet. USBSS IRQ_ENABLE_CLR Register

### 16.5.1.7 IRQDMATHOLDTX00 Register (offset = 100h) [reset = 0h]

IRQDMATHOLDTX00 is shown in [Figure 16-28](#) and described in [Table 16-36](#).

**Figure 16-28. IRQDMATHOLDTX00 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-36. IRQDMATHOLDTX00 Register Field Descriptions**

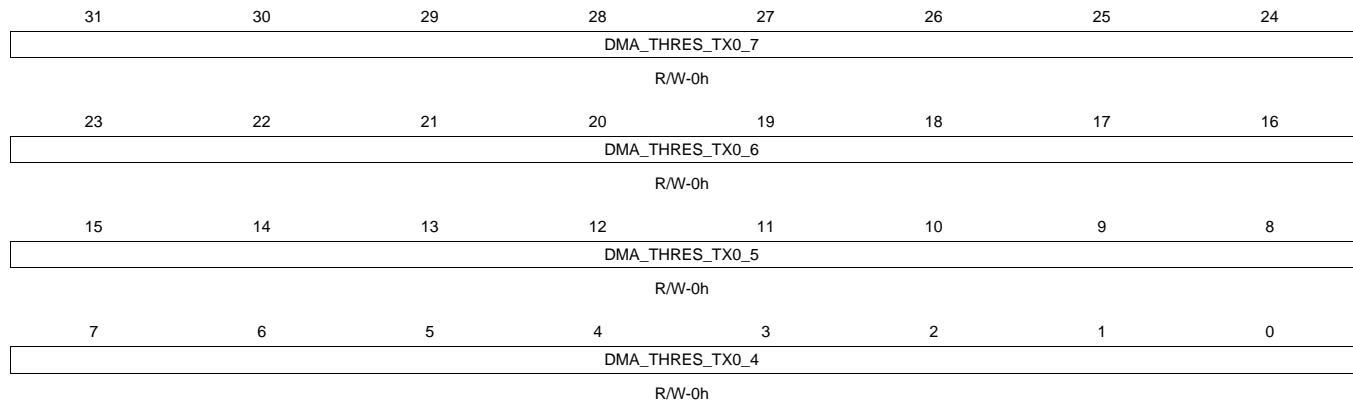

Bit	Field	Type	Reset	Description
31-24	DMA_THRES_TX0_3	R/W	0h	DMA threshold value for tx_pkt_cmp_0 for USB0 Endpoint 3.
23-16	DMA_THRES_TX0_2	R/W	0h	DMA threshold value for tx_pkt_cmp_0 for USB0 Endpoint 2.
15-8	DMA_THRES_TX0_1	R/W	0h	DMA threshold value for tx_pkt_cmp_0 for USB0 Endpoint 1.

### 16.5.1.8 IRQDMATHOLDTX01 Register (offset = 104h) [reset = 0h]

IRQDMATHOLDTX01 is shown in [Figure 16-29](#) and described in [Table 16-37](#).

**Figure 16-29. IRQDMATHOLDTX01 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-37. IRQDMATHOLDTX01 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	DMA_THRES_TX0_7	R/W	0h	DMA threshold value for tx_pkt_cmp_0 for USB0 Endpoint 7.
23-16	DMA_THRES_TX0_6	R/W	0h	DMA threshold value for tx_pkt_cmp_0 for USB0 Endpoint 6.
15-8	DMA_THRES_TX0_5	R/W	0h	DMA threshold value for tx_pkt_cmp_0 for USB0 Endpoint 5.
7-0	DMA_THRES_TX0_4	R/W	0h	DMA threshold value for tx_pkt_cmp_0 for USB0 Endpoint 4. USBSS IRQ_DMA_THRSHOLD_TX0_1 Register

**16.5.1.9 IRQDMATHOLDTX02 Register (offset = 108h) [reset = 0h]**

 IRQDMATHOLDTX02 is shown in [Figure 16-30](#) and described in [Table 16-38](#).

**Figure 16-30. IRQDMATHOLDTX02 Register**

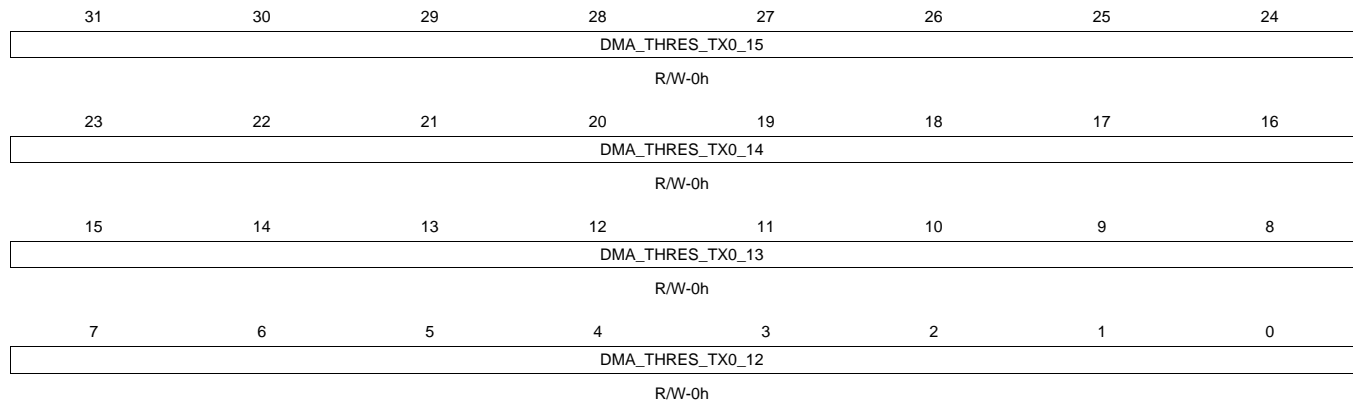

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-38. IRQDMATHOLDTX02 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	DMA_THRES_TX0_11	R/W	0h	DMA threshold value for tx_pkt_cmp_0 for USB0 Endpoint 11.
23-16	DMA_THRES_TX0_10	R/W	0h	DMA threshold value for tx_pkt_cmp_0 for USB0 Endpoint 10.
15-8	DMA_THRES_TX0_9	R/W	0h	DMA threshold value for tx_pkt_cmp_0 for USB0 Endpoint 9.
7-0	DMA_THRES_TX0_8	R/W	0h	DMA threshold value for tx_pkt_cmp_0 for USB0 Endpoint 8. USBSS IRQ_DMA_THRSHOLD_TX0_2 Register

**16.5.1.10 IRQDMATHOLDTX03 Register (offset = 10Ch) [reset = 0h]**

IRQDMATHOLDTX03 is shown in [Figure 16-31](#) and described in [Table 16-39](#).

**Figure 16-31. IRQDMATHOLDTX03 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

Bit	Field	Type	Reset	Description
31-24	DMA_THRES_RX0_15	R/W	0h	DMA threshold value for rx_pkt_cmp_0 for USB0 Endpoint 15.
23-16	DMA_THRES_RX0_14	R/W	0h	DMA threshold value for rx_pkt_cmp_0 for USB0 Endpoint 14.
15-8	DMA_THRES_RX0_13	R/W	0h	DMA threshold value for rx_pkt_cmp_0 for USB0 Endpoint 13.
7-0	DMA_THRES_RX0_12	R/W	0h	DMA threshold value for rx_pkt_cmp_0 for USB0 Endpoint 12. USBSS IRQ_DMA_THRSHOLD_RX0_3 Register

**16.5.1.15 IRQDMATHOLDTX10 Register (offset = 120h) [reset = 0h]**

 IRQDMATHOLDTX10 is shown in [Figure 16-36](#) and described in [Table 16-44](#).

**Figure 16-36. IRQDMATHOLDTX10 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-44. IRQDMATHOLDTX10 Register Field Descriptions**

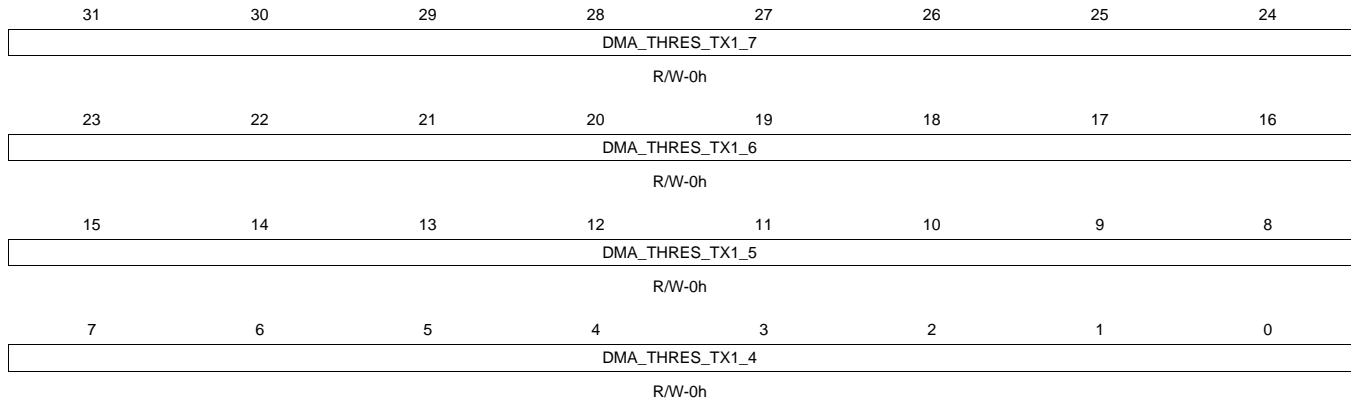

Bit	Field	Type	Reset	Description
31-24	DMA_THRES_TX1_3	R/W	0h	DMA threshold value for tx_pkt_cmp_0 for USB1 Endpoint 3.
23-16	DMA_THRES_TX1_2	R/W	0h	DMA threshold value for tx_pkt_cmp_0 for USB1 Endpoint 2.
15-8	DMA_THRES_TX1_1	R/W	0h	DMA threshold value for tx_pkt_cmp_0 for USB1 Endpoint 1.

### 16.5.1.16 IRQDMATHOLDTX11 Register (offset = 124h) [reset = 0h]

IRQDMATHOLDTX11 is shown in [Figure 16-37](#) and described in [Table 16-45](#).

**Figure 16-37. IRQDMATHOLDTX11 Register**

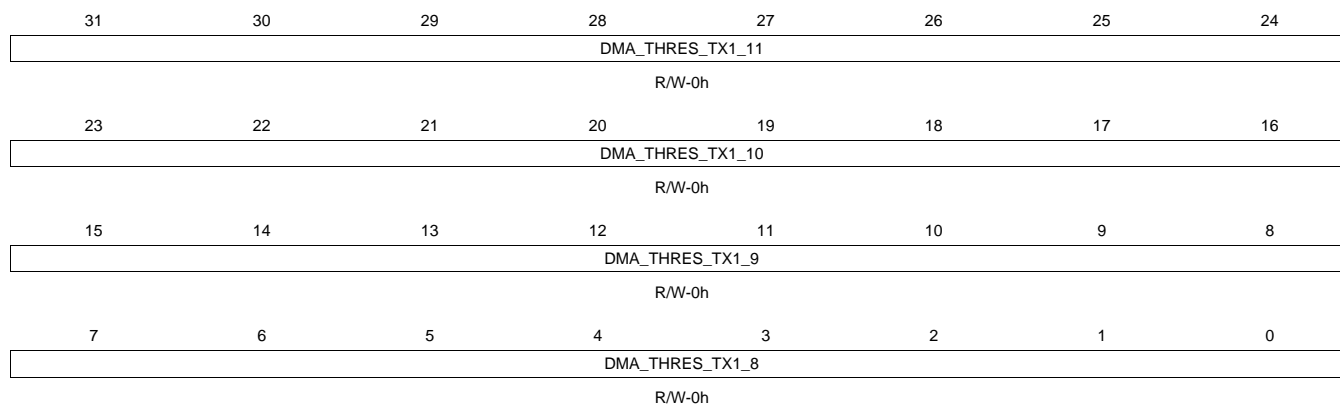

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-45. IRQDMATHOLDTX11 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	DMA_THRES_TX1_7	R/W	0h	DMA threshold value for tx_pkt_cmp_0 for USB1 Endpoint 7.
23-16	DMA_THRES_TX1_6	R/W	0h	DMA threshold value for tx_pkt_cmp_0 for USB1 Endpoint 6.
15-8	DMA_THRES_TX1_5	R/W	0h	DMA threshold value for tx_pkt_cmp_0 for USB1 Endpoint 5.
7-0	DMA_THRES_TX1_4	R/W	0h	DMA threshold value for tx_pkt_cmp_0 for USB1 Endpoint 4. USBSS IRQ_DMA_THRSHOLD_TX1_1 Register

**16.5.1.17 IRQDMATHOLDTX12 Register (offset = 128h) [reset = 0h]**

 IRQDMATHOLDTX12 is shown in [Figure 16-38](#) and described in [Table 16-46](#).

**Figure 16-38. IRQDMATHOLDTX12 Register**

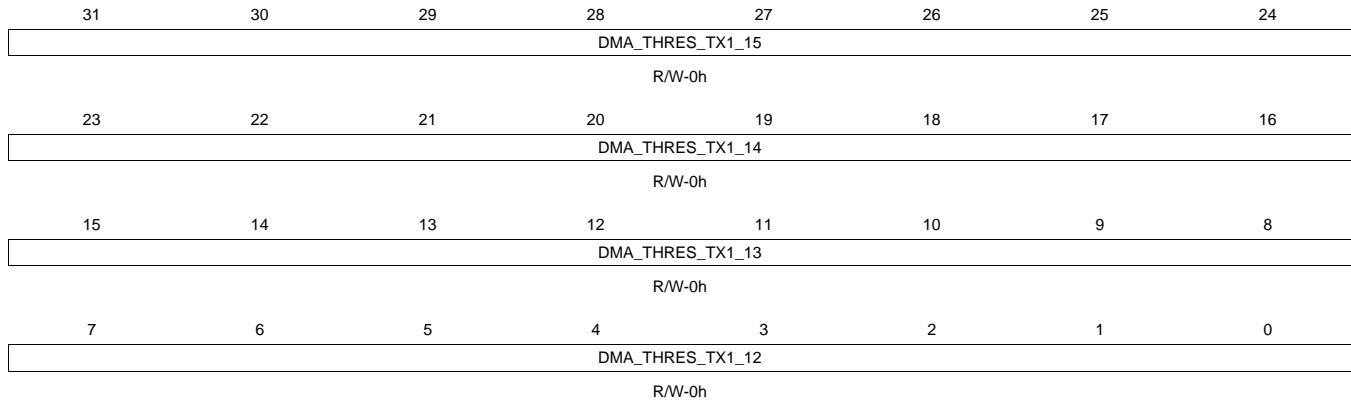

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-46. IRQDMATHOLDTX12 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	DMA_THRES_TX1_11	R/W	0h	DMA threshold value for tx_pkt_cmp_0 for USB1 Endpoint 11.
23-16	DMA_THRES_TX1_10	R/W	0h	DMA threshold value for tx_pkt_cmp_0 for USB1 Endpoint 10.
15-8	DMA_THRES_TX1_9	R/W	0h	DMA threshold value for tx_pkt_cmp_0 for USB1 Endpoint 9.
7-0	DMA_THRES_TX1_8	R/W	0h	DMA threshold value for tx_pkt_cmp_0 for USB1 Endpoint 8. USBSS IRQ_DMA_THRSHOLD_TX1_2 Register

**16.5.1.18 IRQDMATHOLDTX13 Register (offset = 12Ch) [reset = 0h]**

 IRQDMATHOLDTX13 is shown in [Figure 16-39](#) and described in [Table 16-47](#).

**Figure 16-39. IRQDMATHOLDTX13 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-47. IRQDMATHOLDTX13 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	DMA_THRES_TX1_15	R/W	0h	DMA threshold value for tx_pkt_cmp_0 for USB1 Endpoint 15.
23-16	DMA_THRES_TX1_14	R/W	0h	DMA threshold value for tx_pkt_cmp_0 for USB1 Endpoint 14.
15-8	DMA_THRES_TX1_13	R/W	0h	DMA threshold value for tx_pkt_cmp_0 for USB1 Endpoint 13.
7-0	DMA_THRES_TX1_12	R/W	0h	DMA threshold value for tx_pkt_cmp_0 for USB1 Endpoint 12. USBSS IRQ_DMA_THRSHOLD_TX1_3 Register

**16.5.1.19 IRQDMATHOLDRX10 Register (offset = 130h) [reset = 0h]**

 IRQDMATHOLDRX10 is shown in [Figure 16-40](#) and described in [Table 16-48](#).

**Figure 16-40. IRQDMATHOLDRX10 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

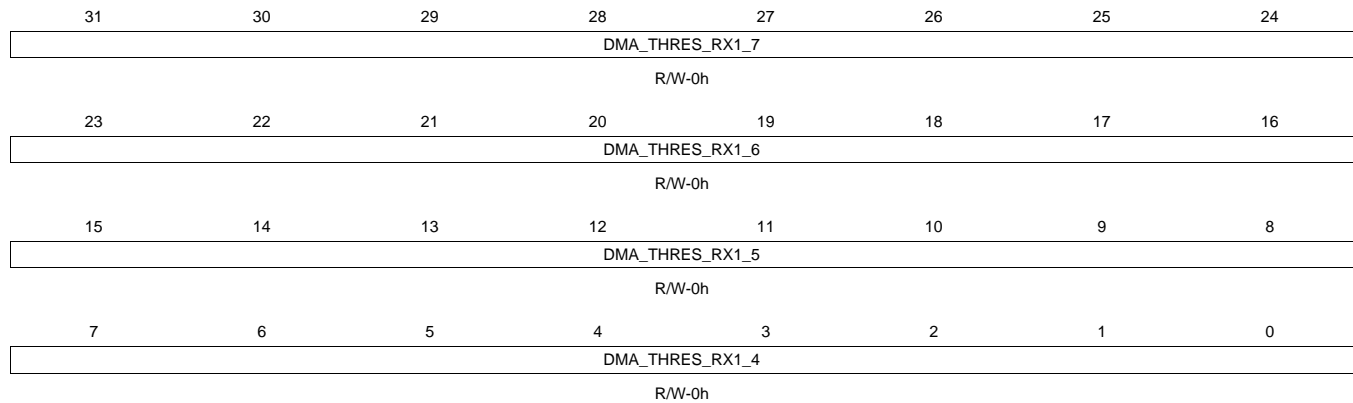

**Table 16-48. IRQDMATHOLDRX10 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	DMA_THRES_RX1_3	R/W	0h	DMA threshold value for rx_pkt_cmp_0 for USB1 Endpoint 3.
23-16	DMA_THRES_RX1_2	R/W	0h	DMA threshold value for rx_pkt_cmp_0 for USB1 Endpoint 2.
15-8	DMA_THRES_RX1_1	R/W	0h	DMA threshold value for rx_pkt_cmp_0 for USB1 Endpoint 1.

### 16.5.1.20 IRQDMATHOLDRX11 Register (offset = 134h) [reset = 0h]

IRQDMATHOLDRX11 is shown in [Figure 16-41](#) and described in [Table 16-49](#).

**Figure 16-41. IRQDMATHOLDRX11 Register**

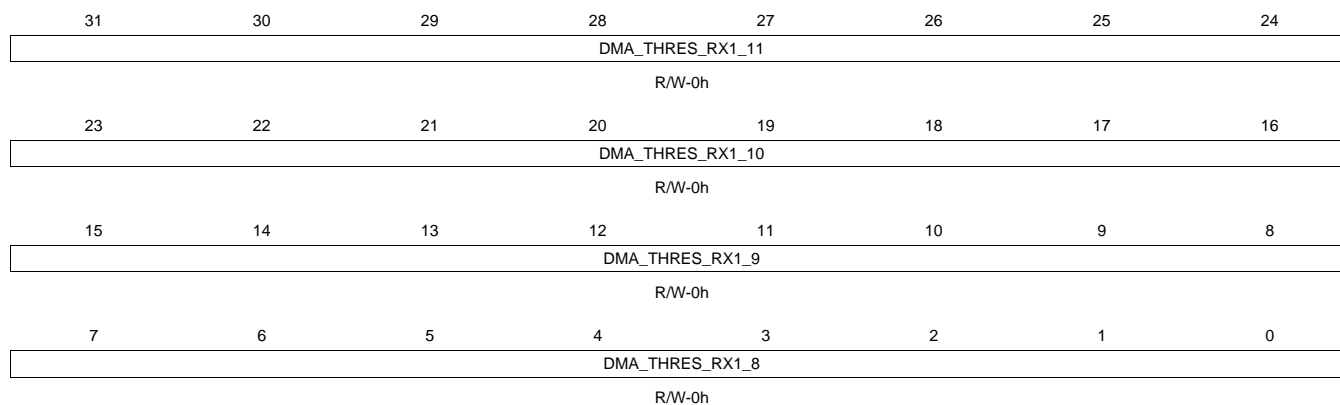

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-49. IRQDMATHOLDRX11 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	DMA_THRES_RX1_7	R/W	0h	DMA threshold value for rx_pkt_cmp_0 for USB1 Endpoint 7.
23-16	DMA_THRES_RX1_6	R/W	0h	DMA threshold value for rx_pkt_cmp_0 for USB1 Endpoint 6.
15-8	DMA_THRES_RX1_5	R/W	0h	DMA threshold value for rx_pkt_cmp_0 for USB1 Endpoint 5.
7-0	DMA_THRES_RX1_4	R/W	0h	DMA threshold value for rx_pkt_cmp_0 for USB1 Endpoint 4. USBSS IRQ_DMA_THRSHOLD_RX1_1 Register

**16.5.1.21 IRQDMATHOLDRX12 Register (offset = 138h) [reset = 0h]**

 IRQDMATHOLDRX12 is shown in [Figure 16-42](#) and described in [Table 16-50](#).

**Figure 16-42. IRQDMATHOLDRX12 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

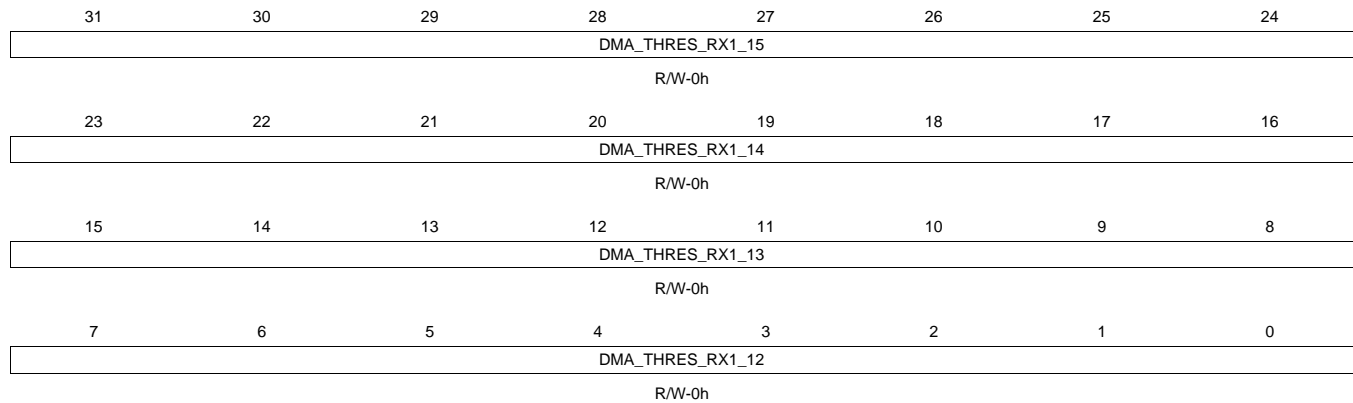

**Table 16-50. IRQDMATHOLDRX12 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	DMA_THRES_RX1_11	R/W	0h	DMA threshold value for rx_pkt_cmp_0 for USB1 Endpoint 11.
23-16	DMA_THRES_RX1_10	R/W	0h	DMA threshold value for rx_pkt_cmp_0 for USB1 Endpoint 10.
15-8	DMA_THRES_RX1_9	R/W	0h	DMA threshold value for rx_pkt_cmp_0 for USB1 Endpoint 9.
7-0	DMA_THRES_RX1_8	R/W	0h	DMA threshold value for rx_pkt_cmp_0 for USB1 Endpoint 8. USBSS IRQ_DMA_THRSHOLD_RX1_2 Register

### 16.5.1.22 IRQDMATHOLDRX13 Register (offset = 13Ch) [reset = 0h]

IRQDMATHOLDRX13 is shown in [Figure 16-43](#) and described in [Table 16-51](#).

**Figure 16-43. IRQDMATHOLDRX13 Register**

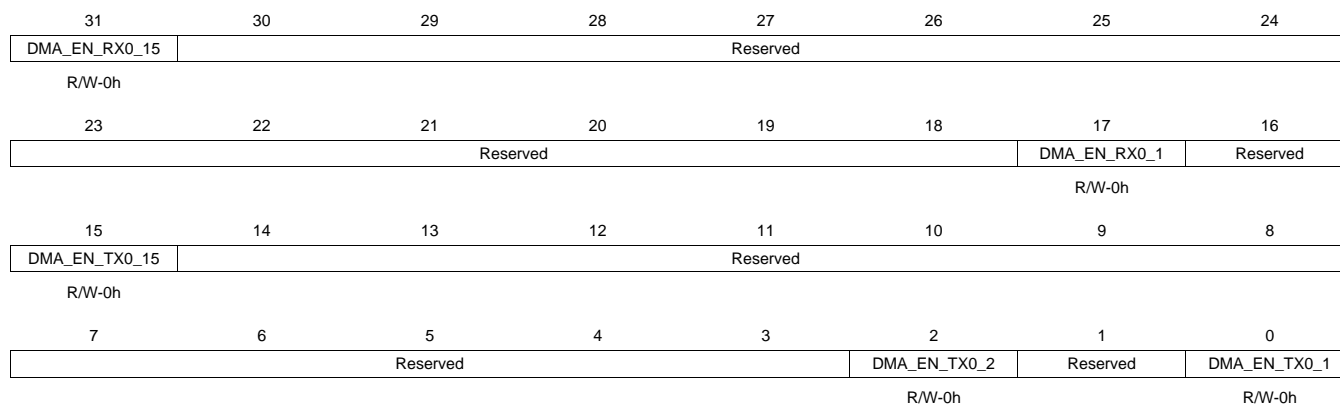

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-51. IRQDMATHOLDRX13 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	DMA_THRES_RX1_15	R/W	0h	DMA threshold value for rx_pkt_cmp_0 for USB1 Endpoint 15.
23-16	DMA_THRES_RX1_14	R/W	0h	DMA threshold value for rx_pkt_cmp_0 for USB1 Endpoint 14.
15-8	DMA_THRES_RX1_13	R/W	0h	DMA threshold value for rx_pkt_cmp_0 for USB1 Endpoint 13.
7-0	DMA_THRES_RX1_12	R/W	0h	DMA threshold value for rx_pkt_cmp_0 for USB1 Endpoint 12. USBSS IRQ_DMA_THRSHOLD_RX1_3 Register

**16.5.1.23 IRQDMAENABLE0 Register (offset = 140h) [reset = 0h]**

 IRQDMAENABLE0 is shown in [Figure 16-44](#) and described in [Table 16-52](#).

**Figure 16-44. IRQDMAENABLE0 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

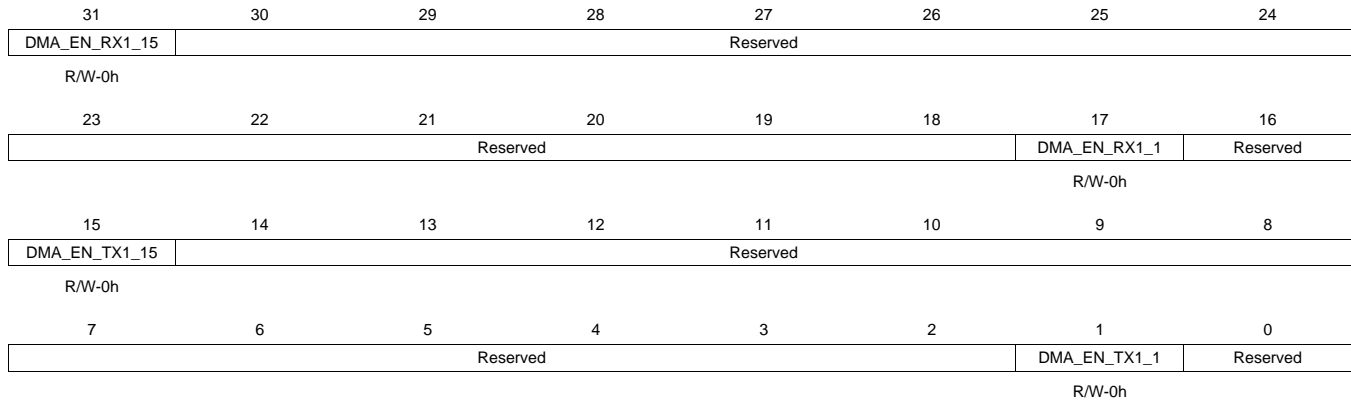

**Table 16-52. IRQDMAENABLE0 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	DMA_EN_RX0_15	R/W	0h	DMA threshold enable value for rx_pkt_cmp_0 for USB0 Endpoint 15. ... ... ... ...
17	DMA_EN_RX0_1	R/W	0h	DMA threshold enable value for rx_pkt_cmp_0 for USB0 Endpoint 1.
15	DMA_EN_TX0_15	R/W	0h	DMA threshold enable value for tx_pkt_cmp_0 for USB0 Endpoint 15. ... ... ... ...
2	DMA_EN_TX0_2	R/W	0h	DMA threshold enable value for tx_pkt_cmp_0 for USB0 Endpoint 2.
0	DMA_EN_TX0_1	R/W	0h	DMA threshold enable value for tx_pkt_cmp_0 for USB0 Endpoint 1.

**16.5.1.24 IRQDMAENABLE1 Register (offset = 144h) [reset = 0h]**

IRQDMAENABLE1 is shown in [Figure 16-45](#) and described in [Table 16-53](#).

**Figure 16-45. IRQDMAENABLE1 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-53. IRQDMAENABLE1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	DMA_EN_RX1_15	R/W	0h	DMA threshold enable value for rx_pkt_cmp_1 for USB1 Endpoint 15. ... ... ... ...
17	DMA_EN_RX1_1	R/W	0h	DMA threshold enable value for rx_pkt_cmp_1 for USB1 Endpoint 1.
15	DMA_EN_TX1_15	R/W	0h	DMA threshold enable value for tx_pkt_cmp_1 for USB1 Endpoint 15. ... ... ... ...
1	DMA_EN_TX1_1	R/W	0h	DMA threshold enable value for tx_pkt_cmp_1 for USB1 Endpoint 1.

**16.5.1.25 IRQFRAMETHOLDTX00 Register (offset = 200h) [reset = 0h]**

 IRQFRAMETHOLDTX00 is shown in [Figure 16-46](#) and described in [Table 16-54](#).

**Figure 16-46. IRQFRAMETHOLDTX00 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

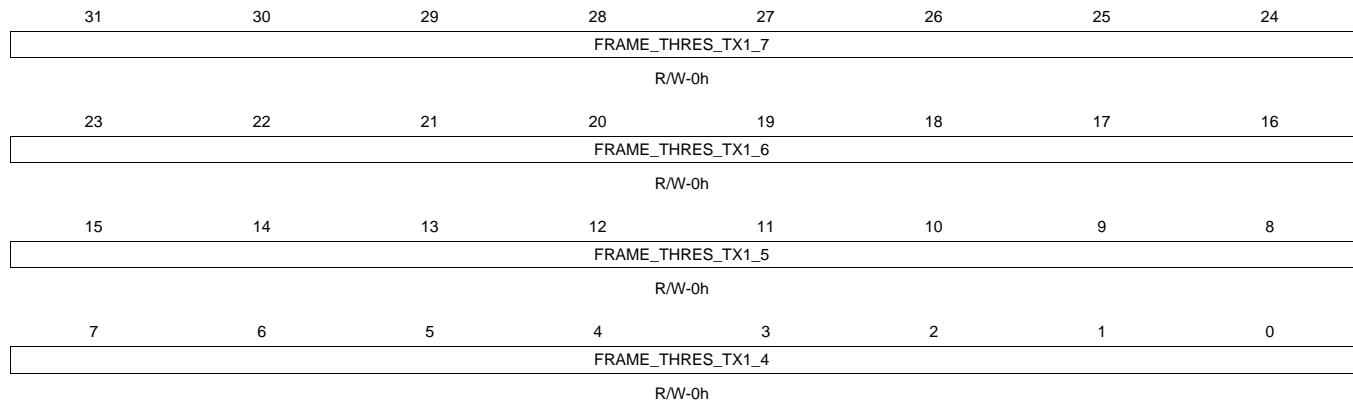

**Table 16-54. IRQFRAMETHOLDTX00 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	FRAME_THRES_TX1_3	R/W	0h	FRAME threshold value for tx_pkt_cmp_0 for USB0 Endpoint 3.
23-16	FRAME_THRES_TX1_2	R/W	0h	FRAME threshold value for tx_pkt_cmp_0 for USB0 Endpoint 2.
15-8	FRAME_THRES_TX1_1	R/W	0h	FRAME threshold value for tx_pkt_cmp_0 for USB0 Endpoint 1.

### 16.5.1.26 IRQFRAMETHOLDTX01 Register (offset = 204h) [reset = 0h]

IRQFRAMETHOLDTX01 is shown in [Figure 16-47](#) and described in [Table 16-55](#).

**Figure 16-47. IRQFRAMETHOLDTX01 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-55. IRQFRAMETHOLDTX01 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	FRAME_THRES_TX1_7	R/W	0h	FRAME threshold value for tx_pkt_cmp_0 for USB0 Endpoint 7.
23-16	FRAME_THRES_TX1_6	R/W	0h	FRAME threshold value for tx_pkt_cmp_0 for USB0 Endpoint 6.
15-8	FRAME_THRES_TX1_5	R/W	0h	FRAME threshold value for tx_pkt_cmp_0 for USB0 Endpoint 5.
7-0	FRAME_THRES_TX1_4	R/W	0h	FRAME threshold value for tx_pkt_cmp_0 for USB0 Endpoint 4. USBSS IRQ_FRAME_THRSHOLD_TX0_1 Register

**16.5.1.27 IRQFRAMETHOLDTX02 Register (offset = 208h) [reset = 0h]**

 IRQFRAMETHOLDTX02 is shown in [Figure 16-48](#) and described in [Table 16-56](#).

**Figure 16-48. IRQFRAMETHOLDTX02 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-56. IRQFRAMETHOLDTX02 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	FRAME_THRES_TX1_11	R/W	0h	FRAME threshold value for tx_pkt_cmp_0 for USB0 Endpoint 11.
23-16	FRAME_THRES_TX1_10	R/W	0h	FRAME threshold value for tx_pkt_cmp_0 for USB0 Endpoint 10.
15-8	FRAME_THRES_TX1_9	R/W	0h	FRAME threshold value for tx_pkt_cmp_0 for USB0 Endpoint 9.
7-0	FRAME_THRES_TX1_8	R/W	0h	FRAME threshold value for tx_pkt_cmp_0 for USB0 Endpoint 8. USBSS IRQ_FRAME_THRSHOLD_TX0_2 Register

### 16.5.1.28 IRQFRAMETHOLDTX03 Register (offset = 20Ch) [reset = 0h]

IRQFRAMETHOLDTX03 is shown in [Figure 16-49](#) and described in [Table 16-57](#).

**Figure 16-49. IRQFRAMETHOLDTX03 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-57. IRQFRAMETHOLDTX03 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	FRAME_THRES_TX1_15	R/W	0h	FRAME threshold value for tx_pkt_cmp_0 for USB0 Endpoint 15.
23-16	FRAME_THRES_TX1_14	R/W	0h	FRAME threshold value for tx_pkt_cmp_0 for USB0 Endpoint 14.
15-8	FRAME_THRES_TX1_13	R/W	0h	FRAME threshold value for tx_pkt_cmp_0 for USB0 Endpoint 13.
7-0	FRAME_THRES_TX1_12	R/W	0h	FRAME threshold value for tx_pkt_cmp_0 for USB0 Endpoint 12. USBSS IRQ_FRAME_THRSHOLD_TX0_3 Register

**16.5.1.29 IRQFRAMETHOLDRX00 Register (offset = 210h) [reset = 0h]**

 IRQFRAMETHOLDRX00 is shown in [Figure 16-50](#) and described in [Table 16-58](#).

**Figure 16-50. IRQFRAMETHOLDRX00 Register**

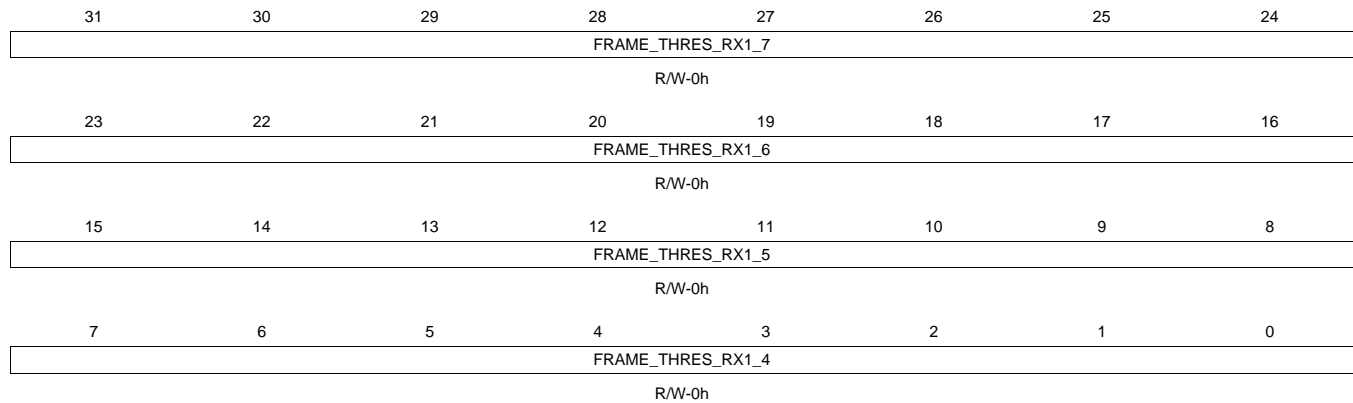

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-58. IRQFRAMETHOLDRX00 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	FRAME_THRES_RX1_3	R/W	0h	FRAME threshold value for rx_pkt_cmp_0 for USB0 Endpoint 3.
23-16	FRAME_THRES_RX1_2	R/W	0h	FRAME threshold value for rx_pkt_cmp_0 for USB0 Endpoint 2.
15-8	FRAME_THRES_RX1_1	R/W	0h	FRAME threshold value for rx_pkt_cmp_0 for USB0 Endpoint 1.

**16.5.1.30 IRQFRAMETHOLDRX01 Register (offset = 214h) [reset = 0h]**

 IRQFRAMETHOLDRX01 is shown in [Figure 16-51](#) and described in [Table 16-59](#).

**Figure 16-51. IRQFRAMETHOLDRX01 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

### 16.5.2.1 USB0REV Register (offset = 0h) [reset = 4EA20800h]

USB0REV is shown in [Figure 16-64](#) and described in [Table 16-73](#).

**Figure 16-64. USB0REV Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-73. USB0REV Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-30	SCHEME	R	1h	Used to distinguish between legacy interface scheme and current. 0 = Legacy 1 = Current
27-16	FUNC	R	EA2h	Function indicates a software compatible module family.
15-11	R_RTL	R	1h	RTL revision. Will vary depending on release.
10-8	X_MAJOR	R	0h	Major revision.
7-6	CUSTOM	R	0h	Custom revision
5-0	Y_MINOR	R	0h	Minor revision. USB0 Revision Register

### 16.5.2.2 USB0CTRL Register (offset = 14h) [reset = 0h]

USB0CTRL is shown in [Figure 16-65](#) and described in [Table 16-74](#).

**Figure 16-65. USB0CTRL Register**

31	30	29	28	27	26	25	24
DIS_DEB	DIS_SRP	Reserved					
R/W-0h	R/W-0h						
23	22	21	20	19	18	17	16
Reserved							
15	14	13	12	11	10	9	8
Reserved							
7	6	5	4	3	2	1	0
Reserved		SOFT_RESET_ISOLATION	RNDIS	UINT	Reserved	CLKFACK	SOFT_RESET
		R/W-0h	R/W-0h	R/W-0h		R/W-0h	R/W-0h

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-74. USB0CTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	DIS_DEB	R/W	0h	Disable the VBUS debouncer circuit fix
30	DIS_SRP	R/W	0h	Disable the OTG Session Request Protocol (SRP) AVALID circuit fix. When enabled (=0) this allows additional time for the VBUS signal to be measured against the VBUS thresholds. The time is specified in the USB0 SRP Fix Time Register.
5	SOFT_RESET_ISOLATION	R/W	0h	Soft reset isolation. When high this bit forces all USB0 signals that connect to the USBSS to known values during a soft reset via bit 0 of this register. This bit should be set high prior to setting bit 0 and cleared after bit 0 is cleared.
4	RNDIS	R/W	0h	Global RNDIS mode enable for all endpoints.
3	UINT	R/W	0h	USB interrupt enable 1 = Legacy 0 = Current (recommended setting) If uint is set high, then the mentor controller generic interrupt for USB[9] will be generated (if enabled). This requires S/W to read the mentor controller's registers to determine which interrupt from USB[0] to USB[7] that occurred. If uint is set low, then the usb20otg_f module will automatically read the mentor controller's registers and set the appropriate interrupt from USB[0] to USB[7] (if enabled). The generic interrupt for USB[9] will not be generated.
1	CLKFACK	R/W	0h	Clock stop fast ack enable.

**Table 16-74. USB0CTRL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	SOFT_RESET	R/W	0h	<p>Software reset of USB0.  Write 0 = no action  Write 1 = Initiate software reset  Read 0 = Reset done, no action  Read 1 = Reset ongoing  Both the soft_reset and soft_reset_isolation bits should be asserted simultaneously.  This will cause the following sequence of actions to occur over multiple cycles:</p> <ul style="list-style-type: none"> <li>- All USB0 output signals will go to a known constant value via multiplexers.</li> </ul> <p>This removes the possibility of timing errors due to the asynchronous resets.</p> <ul style="list-style-type: none"> <li>- All USB0 registers will be reset.</li> <li>- The USB0 resets will be de-asserted.</li> <li>- The reset isolation multiplexer inputs will be de-selected.</li> <li>- Both the soft_reset and soft_reset_isolation bits will be automatically cleared.</li> </ul> <p>Setting only the soft_reset_isolation bit will cause all USB0 output signals to go to a known constant value via multiplexers.  This will prevent future access to USB0.  To clear this condition the USBSS must be reset via a hard or soft reset.</p>

### 16.5.2.3 USB0STAT Register (offset = 18h) [reset = 0h]

USB0STAT is shown in [Figure 16-66](#) and described in [Table 16-75](#).

**Figure 16-66. USB0STAT Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-75. USB0STAT Register Field Descriptions**

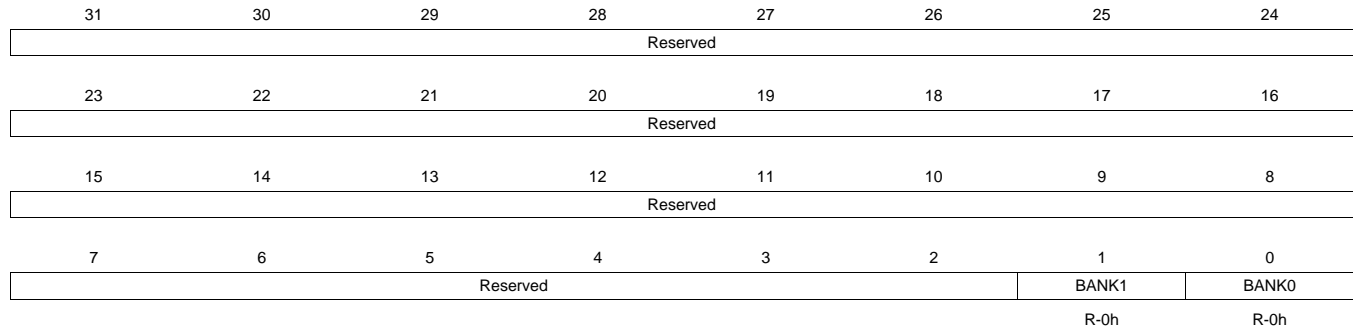

Bit	Field	Type	Reset	Description
0	DRVVBUS	R	0h	Current DRVVBUS value USB0 Status Register

### 16.5.2.4 USB0IRQMSTAT Register (offset = 20h) [reset = 0h]

USB0IRQMSTAT is shown in [Figure 16-67](#) and described in [Table 16-76](#).

**Figure 16-67. USB0IRQMSTAT Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-86. USB0RXMODE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
				RXMAXP and RXCOUNT are both registers within the Mentor controller. * The XDMA will continue to request RX packets from the Mentor controller until a short packet is received. * When the CPPI is configured for chaining mode, the Buffer Descriptor sizes must be integer multiples of the RXMAXP size. * Transmit mode is not supported. * USB0 or USB1 Auto Req register should be set to AUTO REQ ALWAYS.

### 16.5.3.1 USB1REV Register (offset = 0h) [reset = 4EA20800h]

USB1REV is shown in [Figure 16-99](#) and described in [Table 16-109](#).

**Figure 16-99. USB1REV Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-109. USB1REV Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-30	SCHEME	R	1h	Used to distinguish between legacy interface scheme and current. 0 = Legacy 1 = Current
27-16	FUNC	R	EA2h	Function indicates a software compatible module family.
15-11	R_RTL	R	1h	RTL revision. Will vary depending on release.
10-8	X_MAJOR	R	0h	Major revision.
7-6	CUSTOM	R	0h	Custom revision
5-0	Y_MINOR	R	0h	Minor revision. USB1 Revision Register

### 16.5.3.2 USB1CTRL Register (offset = 14h) [reset = 0h]

USB1CTRL is shown in [Figure 16-100](#) and described in [Table 16-110](#).

**Figure 16-100. USB1CTRL Register**

31	30	29	28	27	26	25	24
DIS_DEB	DIS_SRP	Reserved					
R/W-0h	R/W-0h						
23	22	21	20	19	18	17	16
Reserved							
15	14	13	12	11	10	9	8
Reserved							
7	6	5	4	3	2	1	0
Reserved		SOFT_RESET_ISOLATION	RNDIS	UINT	Reserved	CLKFACK	SOFT_RESET
		R/W-0h	R/W-0h	R/W-0h		R/W-0h	R/W-0h

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-110. USB1CTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	DIS_DEB	R/W	0h	Disable the VBUS debouncer circuit fix
30	DIS_SRP	R/W	0h	Disable the OTG Session Request Protocol (SRP) AVALID circuit fix. When enabled (=0) this allows additional time for the VBUS signal to be measured against the VBUS thresholds. The time is specified in the USB0 SRP Fix Time Register.
5	SOFT_RESET_ISOLATION	R/W	0h	Soft reset isolation. When high this bit forces all USB1 signals that connect to the USBSS to known values during a soft reset via bit 0 of this register. This bit should be set high prior to setting bit 0 and cleared after bit 0 is cleared.
4	RNDIS	R/W	0h	Global RNDIS mode enable for all endpoints.
3	UINT	R/W	0h	USB interrupt enable 1 = Legacy 0 = Current (recommended setting) If uint is set high, then the mentor controller generic interrupt for USB[9] will be generated (if enabled). This requires S/W to read the mentor controller's registers to determine which interrupt from USB[0] to USB[7] that occurred. If uint is set low, then the usb20otg_f module will automatically read the mentor controller's registers and set the appropriate interrupt from USB[0] to USB[7] (if enabled). The generic interrupt for USB[9] will not be generated.
1	CLKFACK	R/W	0h	Clock stop fast ack enable.

**Table 16-110. USB1CTRL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	SOFT_RESET	R/W	0h	<p>Software reset of USB1.            Write 0 = no action            Write 1 = Initiate software reset            Read 0 = Reset done, no action            Read 1 = Reset ongoing            Both the soft_reset and soft_reset_isolation bits should be asserted simultaneously.            This will cause the following sequence of actions to occur over multiple cycles:</p> <ul style="list-style-type: none"> <li>- All USB0 output signals will go to a known constant value via multiplexers.</li> </ul> <p>This removes the possibility of timing errors due to the asynchronous resets.</p> <ul style="list-style-type: none"> <li>- All USB0 registers will be reset.</li> <li>- The USB0 resets will be de-asserted.</li> <li>- The reset isolation multiplexer inputs will be de-selected.</li> <li>- Both the soft_reset and soft_reset_isolation bits will be automatically cleared.</li> </ul> <p>Setting only the soft_reset_isolation bit will cause all USB0 output signals to go to a known constant value via multiplexers.            This will prevent future access to USB0.            To clear this condition the USBSS must be reset via a hard or soft reset.</p>

### 16.5.3.3 USB1STAT Register (offset = 18h) [reset = 0h]

USB1STAT is shown in [Figure 16-101](#) and described in [Table 16-111](#).

**Figure 16-101. USB1STAT Register**

Bit	Field	Type	Reset	Description
31-17	TX_TDOWN	R/W	0h	Tx Endpoint Teardown. Write '1' to corresponding bit to set. Read as '0'. Bit 31 = Endpoint 15 ... Bit 17 = Endpoint 1
15-1	RX_TDOWN	R/W	0h	RX Endpoint Teardown. Write '1' to corresponding bit to set. Read as '0'. Bit 15 = Endpoint 15 ... Bit 1 = Endpoint 1

### 16.5.3.33 USB1UTMI Register (offset = E0h) [reset = 200002h]

USB1UTMI is shown in [Figure 16-131](#) and described in [Table 16-141](#).

**Figure 16-131. USB1UTMI Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-141. USB1UTMI Register Field Descriptions**

Bit	Field	Type	Reset	Description
23	TXBITSTUFFEN	R/W	0h	PHY UTMI input for signal txbitstufen
22	TXBITSTUFFENH	R/W	0h	PHY UTMI input for signal txbitstuffenh
21	OTGDISABLE	R/W	1h	PHY UTMI input for signal otgdisable
20	VBUSVLDEXTSEL	R/W	0h	PHY UTMI input for signal vbusvldextsel
19	VBUSVLDEXT	R/W	0h	PHY UTMI input for signal vbusvldext
18	TXENABLEN	R/W	0h	PHY UTMI input for signal txenablen
17	FSXCVROWNER	R/W	0h	PHY UTMI input for signal fsxcvrowner
16	TXVALIDH	R/W	0h	PHY UTMI input for signal txvalidh
15-8	DATAINH	R/W	0h	PHY UTMI input for signal datainh
2	WORDINTERFACE	R/W	0h	PHY UTMI input for signal wordinterface
1	FSDATAEXT	R/W	1h	PHY UTMI input for signal fsdataext
0	FSSE0EXT	R/W	0h	PHY UTMI input for signal fsse0ext USB1 PHY UTMI Register

**16.5.3.34 USB1UTMILB Register (offset = E4h) [reset = 82h]**

USB1UTMILB is shown in [Figure 16-132](#) and described in [Table 16-142](#).

### 16.5.4.1 Termination\_control Register (offset = 0h) [reset = 1000800h]

Termination\_control is shown in [Figure 16-134](#) and described in [Table 16-145](#).

contains bits related to control of terminations in USB2PHY

**Figure 16-134. Termination\_control Register**

31	30	29	28	27	26	25	24
Reserved		ALWAYS_UPDATE	RTERM_CAL_DONE	FS_CODE_SEL			
R/W-0h		R/W-0h	R-0h	R/W-1h

Reserved		USE_RTERM_RMX_REG	RTERM_RMX				
R/W-0h		R/W-0h	R/W-0h				
15	14	13	12	11	10	9	8
RTERM_RMX		HS_CODE_SEL			RTERM_COMP_OUT	RESTART_RTERM_CAL	DISABLE_TEMP_TRACK
R/W-0h		R/W-1h			R-0h	R/W-0h	R/W-0h
7	6	5	4	3	2	1	0
USE_RTERM_CAL_REG	RTERM_CAL						
R/W-0h	R/W-0h						

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-145. Termination\_control Register Field Descriptions**

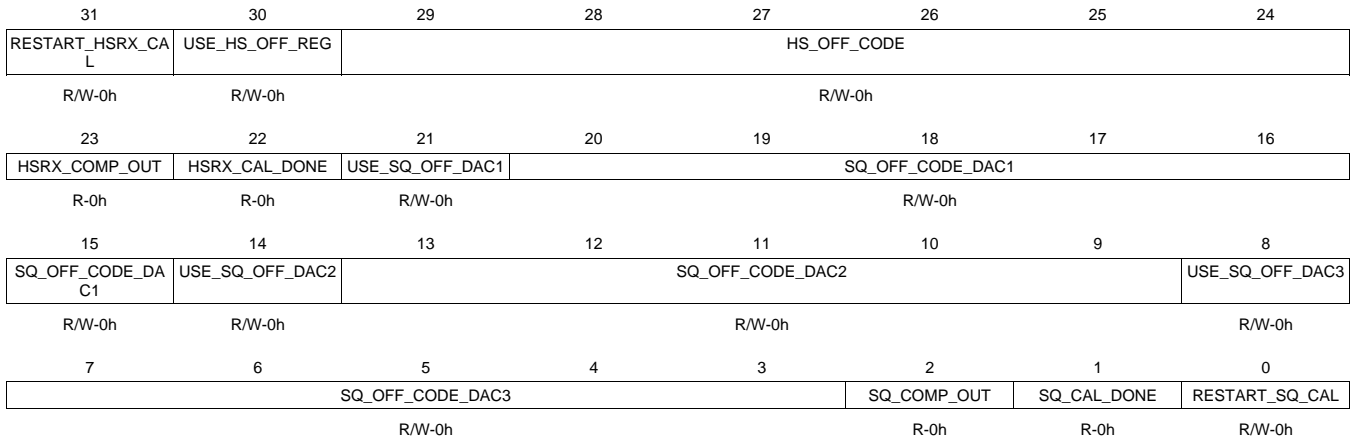

Bit	Field	Type	Reset	Description
31-30	Reserved	R/W	0h	
29	ALWAYS_UPDATE	R/W	0h	When set to 1, the calibration code is updated immediately after a code computation without waiting for idle periods.
28	RTERM_CAL_DONE	R	0h	Rterm calibration is done. 1st time cal is done this bit gets set and gets reset at a restart cal. Read value is valid only if VDDLDO is on.
27-24	FS_CODE_SEL	R/W	1h	FS Code selection control
23-22	Reserved	R/W	0h	
21	USE_RTERM_RMX_REG	R/W	0h	Override termination resistor trim code with RTERM_RMX from this register
20-14	RTERM_RMX	R/W	0h	When read, this field returns the current Termination resistor trim code. Read value is valid only if VDDLDO is on. The value written to this field is used as Termination resistor trim code if bit 21 is set to 1
13-11	HS_CODE_SEL	R/W	1h	HS Code selection control. Each increment increases the termination impedance by ~1.5%. Valid values are 000b 011b.
10	RTERM_COMP_OUT	R	0h	Master loop comparator output. Read value is valid only if VDDLDO is on.
9	RESTART_RTERM_CAL	R/W	0h	Restart the rterm calibration. The calibration restarts on any toggle 0 to 1 or 1 to 0 on this bit.
8	DISABLE_TEMP_TRACK	R/W	0h	Disables the temperature tracking function of the termination calibration
7	USE_RTERM_CAL_REG	R/W	0h	when '1' the rterm cal code is overridden by values in RTERM_CAL
6-0	RTERM_CAL	R/W	0h	When read this field returns the current rterm calibration code. Read value is valid only if VDDLDO is on. The value written to this field is used as rterm calibration code if the bit USE_RTERM_CAL_REG is 1.

### 16.5.4.2 RX\_CALIB Register (offset = 4h) [reset = 0h]

RX\_CALIB is shown in Figure 16-135 and described in Table 16-146.

Contains bits related to RX calibration

**Figure 16-135. RX\_CALIB Register**

LEGEND: R/W = Read/Write; R = Read only; W1toC1 = Write 1 to clear bit; -n = value after reset

**Table 16-146. RX\_CALIB Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	RESTART_HSRX_CAL	R/W	0h	Restart the HSRX calibration state machine when this bit goes from 0 to 1.
30	USE_HS_OFF_REG	R/W	0h	Override HS offset correction with HS_OFF_CODE when set to '1'
29-24	HS_OFF_CODE	R/W	0h	HS offset code, this code is forced when bit 30 is 1 . Code is updated from calibration logic when bit 30 = 0.
23	HSRX_COMP_OUT	R	0h	The output of the HSRX comparator.Read value is valid only if VDDLDO is on.
22	HSRX_CAL_DONE	R	0h	Signal that indicates that the HSRX calibration is done. This gets reset at every restart.Read value is valid only if VDDLDO is on.
21	USE_SQ_OFF_DAC1	R/W	0h	Override Squelch offset DAC1 code when '1'
20-15	SQ_OFF_CODE_DAC1	R/W	0h	When read returns current Sq offset code for DAC1, if VDDLDO is on. When written this is used as Sq offset code for DAC1 when USE_SQ_OFF_DAC 1 = '1'
14	USE_SQ_OFF_DAC2	R/W	0h	Override Squelch offset DAC2 code when '1'
13-9	SQ_OFF_CODE_DAC2	R/W	0h	When read returns current Sq offset code for DAC2, if VDDLDO is on. When written this is used as Sq offset code for DAC2 when USE_SQ_OFF_DAC 2 = '1'
8	USE_SQ_OFF_DAC3	R/W	0h	Override Squelch offset DAC3 code when '1'
7-3	SQ_OFF_CODE_DAC3	R/W	0h	When read returns current Sq offset code for DAC3, if VDDLDO is on. When written this is used as Sq offset code for DAC3 when USE_SQ_OFF_DAC 3 = '1'
2	SQ_COMP_OUT	R	0h	Sq comp output.Read value is valid only if VDDLDO is on.

**Table 16-146. RX\_CALIB Register Field Descriptions (continued)**

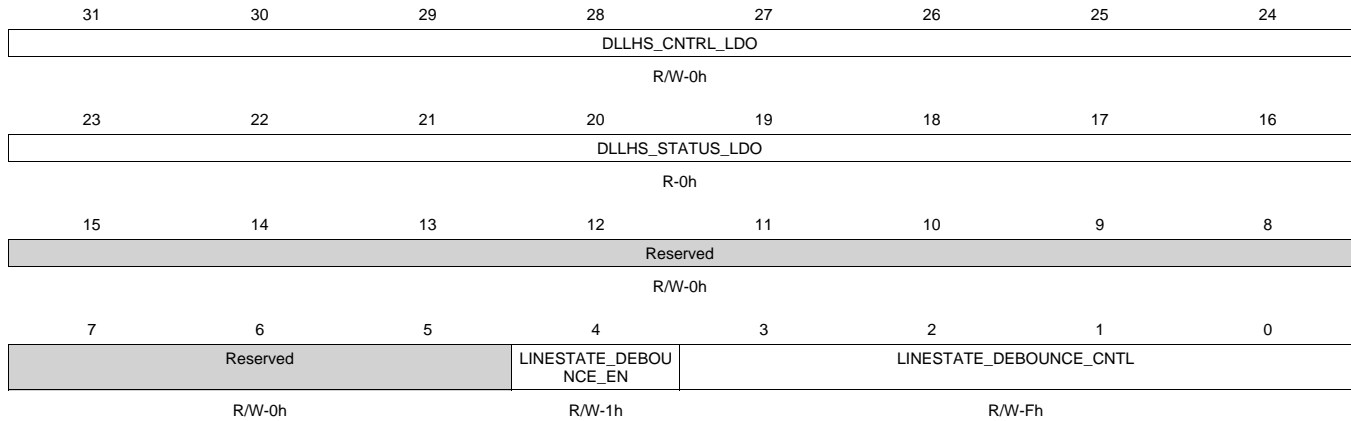

Bit	Field	Type	Reset	Description
1	SQ_CAL_DONE	R	0h	Sq calibration is done when this bit = 1. see RESTART_SQ_CAL for more description. Read value is valid only if VDDLDO is on.
0	RESTART_SQ_CAL	R/W	0h	the squelch calibration continuously goes through restart cycles when this bit is 1 . i.e. restarts waits for done then restarts again etc.

### 16.5.4.3 DLLHS\_2 Register (offset = 8h) [reset = 1Fh]

DLLHS\_2 is shown in [Figure 16-136](#) and described in [Table 16-147](#).

the 2nd DLLHS control register. bits 4:0 are unrelated to the DLLHS and are linestate filter settings

**Figure 16-136. DLLHS\_2 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-147. DLLHS\_2 Register Field Descriptions**

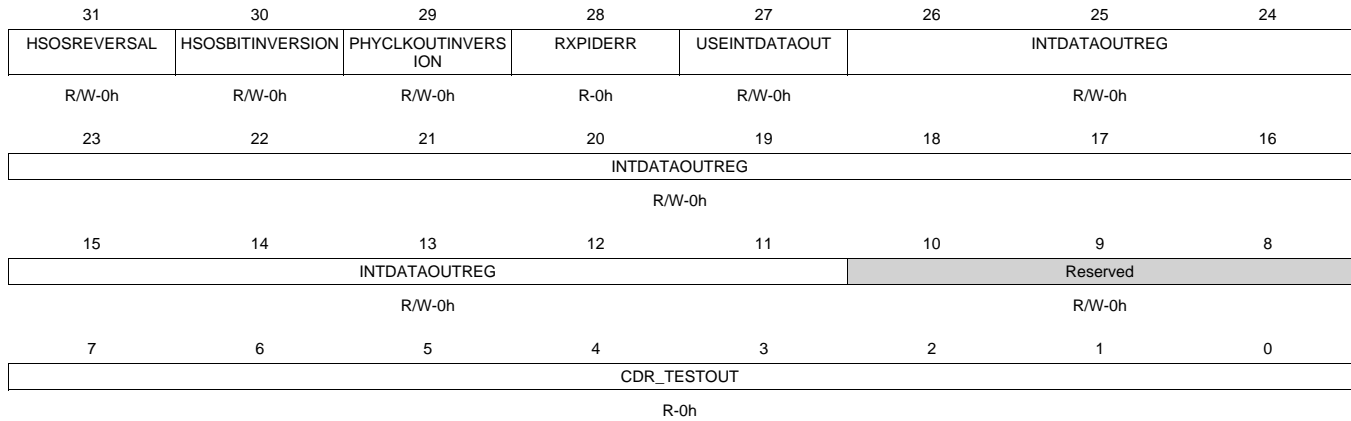

Bit	Field	Type	Reset	Description
31-24	DLLHS_CNTRL_LDO	R/W	0h	See DFT spec for details
23-16	DLLHS_STATUS_LDO	R	0h	See DFT spec for details
15-5	Reserved	R/W	0h	
4	LINESTATE_DEBOUNCE_EN	R/W	1h	Enables the linestate debounce filter
3-0	LINESTATE_DEBOUNCE_CNTL	R/W	Fh	Used for control of the linestate debounce filter when going from synchronous to async linestate.

#### 16.5.4.4 RX\_TEST\_2 Register (offset = Ch) [reset = 0h]

RX\_TEST\_2 is shown in [Figure 16-137](#) and described in [Table 16-148](#).

the 2nd receiver test register

**Figure 16-137. RX\_TEST\_2 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-148. RX\_TEST\_2 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	HSOSREVERSAL	R/W	0h	Swaps the dataout from HSOS
30	HSOSBITINVERSION	R/W	0h	Inverts the HSOS bits
29	PHYCLKOUTINVERSION	R/W	0h	This inverts the phase for the PHYCLKOUT
28	RXPIDERR	R	0h	Flags if the RX data packet has PID error. NOT IMPLEMENTED YET
27	USEINTDATAOUT	R/W	0h	This will bypass the analog and will send data packet to controller incase of receiver (Faking the receive data). data used will be INTDATAOUTREG
26-11	INTDATAOUTREG	R/W	0h	This register will be loaded through OCP and this data will be given to the controller if USEINTDATAOUT is set to 1
10-8	Reserved	R/W	0h	
7-0	CDR_TESTOUT	R	0h	CDR debug bits. Read value is valid only if VDDLDO is on. see DFT spec for details

### 16.5.4.5 CHRГ\_DET Register (offset = 14h) [reset = 0h]

CHRГ\_DET is shown in Figure 16-138 and described in Table 16-149.

this is the charger detect register. this register is not used in the dead battery case.

**Figure 16-138. CHRГ\_DET Register**

31		30		29		28		27		26		25		24

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-149. CHRГ\_DET Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-30	Reserved	R/W	0h	
29	USE_CHG_DET_REG	R/W	0h	Use bits 28-24 and 18-17 from this register
28	DIS_CHG_DET	R/W	0h	When read, returns current value of charger detect input. When USE_CHG_DET_REG = 1, the value written to this field overrides the corresponding charger detect input.
27	SRC_ON_DM	R/W	0h	When read, returns current value of charger detect input. When USE_CHG_DET_REG = 1, the value written to this field overrides the corresponding charger detect input.
26	SINK_ON_DP	R/W	0h	When read, returns current value of charger detect input. When USE_CHG_DET_REG = 1, the value written to this field overrides the corresponding charger detect input.
25	CHG_DET_EXT_CTL	R/W	0h	When read, returns current value of charger detect input. When USE_CHG_DET_REG = 1, the value written to this field overrides the corresponding charger detect input.
24	RESTART_CHG_DET	R/W	0h	Restart the charger detection protocol when this goes from 0 to 1
23	CHG_DET_DONE	R	0h	Charger detect protocol has completed
22	CHG_DETECTED	R	0h	Same signal as CE
21	DATA_DET	R	0h	Output of the data det comparator
20-19	Reserved	R/W	0h	
18	CHG_ISINK_EN	R/W	0h	When read, returns current value of charger detect input. When USE_CHG_DET_REG = 1, the value written to this field overrides the corresponding charger detect input.
17	CHG_VSRC_EN	R/W	0h	When read, returns current value of charger detect input. When USE_CHG_DET_REG = 1, the value written to this field overrides the corresponding charger detect input.
16	COMP_DP	R	0h	Comparator on the DP line value
15	COMP_DM	R	0h	Comparator on the DM line value
14-13	CHG_DET_OSC_CNTRL	R/W	0h	Charger detect osc control

**Table 16-149. CHRГ\_DET Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
12-7	CHG_DET_TIMER	R/W	0h	Charger detect timer control. See charger detect section for details
6-5	Reserved	R/W	0h	
4-3	CHG_DET_ICTRL	R/W	0h	Charger detect current control
2-1	CHG_DET_VCTRL	R/W	0h	Charger detect voltage buffer control
0	FOR_CE	R/W	0h	Force CE = 1 when this bit is set

**16.5.4.6 PWR\_CNTL Register (offset = 18h) [reset = 400000h]**

PWR\_CNTL is shown in Figure 16-139 and described in Table 16-150.

has all the power control bits

**Figure 16-139. PWR\_CNTL Register**

31	30	29	28	27	26	25	24

R/W-0h	R-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-150. PWR\_CNTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	RESETDONETCLK	R	0h	Goes high when the RESET is synchronized to TCLK
30	RESET_DONE_VMAIN	R	0h	Goes high when LDO domain is up and PLL LOCK is available and utmi_reset is de-asserted.
29	VMAIN_GLOBAL_RE SET_DONE	R	0h	Goes high when LDO domain is up and PLL LOCK is available.
28	RESETDONEMCLK	R	0h	Goes high when the RESET is synchronized to MCLK
27	RESETDONE_CHGDET	R	0h	Goes high when the RESET is synchronized to charger detect oscillator clock domain
26-12	LDOPWRCOUNTER	R/W	400h	This is the value of the counter used for LDO power up. RESET to default.
11	FORCEPLLSLOWCLK	R/W	0h	Forces the PLL to the slow clk mode
10	FORCELDOON	R/W	0h	Forces the LDO to be ON.
9	FORCEPLLON	R/W	0h	Forces the PLL to be ON.
8-7	Reserved	R/W	0h	
6	PLLLOCK	R	0h	Lock signal from the PLL
5	USEPLLLOCK	R/W	0h	This signal is used to indicate to the Phy, not to do any clock related activity until PLLLOCK = 1. This is not the default option. 0 do not use PLLLOCK. 1 use PLLLOCK as a clock gate.
4	USE_DATAPOLARITYN REG	R/W	0h	1 -andgt use bit 3 as override for the DATAPOLARITYN signal.
3	DATAPOLARITYN	R/W	0h	Override value of datapolarityn
2	USE_PD_REG	R/W	0h	Use bit 1 from this register as PD override when set to '1'
1	PD	R/W	0h	Override value for PD
0	Reserved	R/W	0h	

**16.5.4.7 UTMI\_INTERFACE\_CNTL\_1 Register (offset = 1Ch) [reset = 0h]**

 UTMI\_INTERFACE\_CNTL\_1 is shown in [Figure 16-140](#) and described in [Table 16-151](#).

register to override UTMI interface control pins.

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-153. BIST Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	BIST_START	R/W	0h	When set to 1 the BIST mode is started.
30	REDUCED_SWING	R/W	0h	When 1 the TX swing is reduced in BIST mode
29	BIST_CRC_CALC_EN	R/W	0h	Enables CRC calculation during BIST when set to 1
28-20	BIST_PKT_LENGTH	R/W	0h	Address for which BIST to select
19	LOOPBACK_EN	R/W	0h	Enables the loopback mode
18-16	BIST_OP_PHASE_SEL	R/W	0h	Selects which phase to use for data transmission during BIST
15	SWEEP_EN	R/W	0h	Enables freq sweep on CDR
14-12	SWEEP_MODE	R/W	0h	Selects the freq sweep mode. Details in DFT spec.
11	BIST_PASS	R	0h	Indicates that the BIST has passed. Read value is valid only if VDDLDO is on.
10	BIST_BUSY	R	0h	Indicates that BIST is running. Read value is valid only if VDDLDO is on.
9-7	Reserved	R/W	0h	
6-5	OP_CODE	R/W	0h	Defined in DFT spec
4	RX_TEST_MODE	R/W	0h	Defined in DFT spec
3	Reserved	R/W	0h	
2	INTER_PKT_DELAY_TEST	R/W	0h	Defined in DFT spec
1	HS_ALL_ONES_TEST	R/W	0h	Defined in DFT spec
0	USE_BIST_TX_PHASES	R/W	0h	When set to 1 bits 18-16 are activated for choosing the transmitting phase.

**16.5.4.10 BIST\_CRC Register (offset = 28h) [reset = 0h]**

BIST\_CRC is shown in [Figure 16-143](#) and described in [Table 16-154](#).

the CRC code for BIST test

**Figure 16-143. BIST\_CRC Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

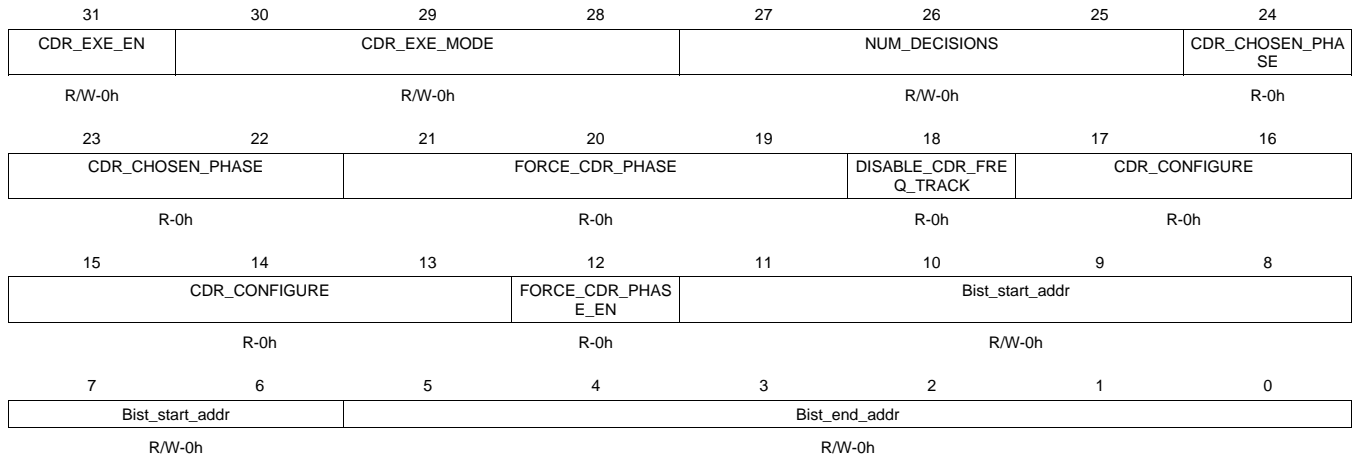

**Table 16-154. BIST\_CRC Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	BIST_CRC	R/W	0h	The CRC value from the BIST.

**16.5.4.11 CDR\_BIST2 Register (offset = 2Ch) [reset = 0h]**

 CDR\_BIST2 is shown in [Figure 16-144](#) and described in [Table 16-155](#).

clock data recovery register and BIST register 2

**Figure 16-144. CDR\_BIST2 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-157. DLLHS Register Field Descriptions**

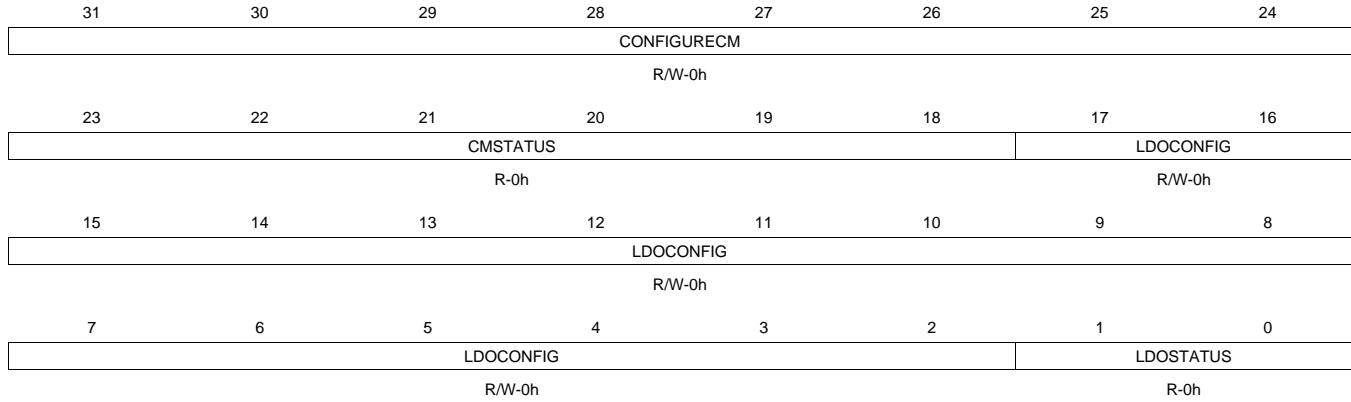

Bit	Field	Type	Reset	Description
31-29	Reserved	R/W	0h	
28	DLLHS_LOCK	R	0h	Read the AFE output by this name
27-22	DLLHS_GENERATED_CODE	R	0h	Read the AFE output by this name. Read value is valid only if VDDLDO is on.
21	DLL_SEL_CODE_PHS	R/W	0h	Connect to DLLHS_TEST_LDO[0] on AFE interface. see DFT spec for details.
20-19	DLL_LOCKCHK	R/W	0h	Connect to DLLHS_TEST_LDO [2:1] on AFE interface. see DFT spec for details.
18-16	DLL_SEL_COD	R/W	0h	Connect to DLLHS_TEST_LDO [5:3] on AFE interface. see DFT spec for details.
15	DLL_PHS0_8	R/W	1h	Connect to DLLHS_TEST_LDO[6] on AFE interface. see DFT spec for details.
14-9	DLL_FORCED_CODE	R/W	0h	Connect to the pin of this name on AFE interface. see DFT spec for details.
8	FORCE_DLL_CODE	R/W	0h	Connect to DLLHS_TEST_LDO[11] on AFE interface. see DFT spec for details.
7-6	DLL_RATE	R/W	0h	Connect to DLLHS_TEST_LDO [8:7] on AFE interface. see DFT spec for details.
5-4	DLL_FILT	R/W	0h	Connect to DLLHS_TEST_LDO [10:9] on AFE interface. see DFT spec for details.
3	DLL_CDR_MODE	R/W	0h	Connect to the pin of this name on AFE interface. see DFT spec for details.
2	DLL_IDLE	R/W	0h	Connect to DLLHS_TEST_LDO[12] on AFE interface. see DFT spec for details.
1	DLL_FREEZE	R/W	0h	Connect to DLLHS_TEST_LDO[13] on AFE interface. see DFT spec for details.
0	Reserved	R/W	0h	

**16.5.4.14 USB2PHYCM\_CONFIG Register (offset = 3Ch) [reset = 0h]**

USB2PHYCM\_CONFIG is shown in [Figure 16-147](#) and described in [Table 16-158](#).

Config and status register for the USB2PHYCM and LDO

**Figure 16-147. USB2PHYCM\_CONFIG Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-158. USB2PHYCM\_CONFIG Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	CONFIGURECM	R/W	0h	Connects to the CONFIGURECM pins. see DFT spec for details.
23-18	CMSTATUS	R	0h	Reads the CMSTATUS bits. see DFT spec for details.
17-2	LDOCONFIG	R/W	0h	The LDOCONFIG bit settings. See DFT spec for details.
1-0	LDOSTATUS	R	0h	Reads the LDOSTATUS bits. see DFT spec for details.

**16.5.4.15 AD\_INTERFACE\_REG1 Register (offset = 44h) [reset = 0h]**

AD\_INTERFACE\_REG1 is shown in [Figure 16-148](#) and described in [Table 16-159](#).

All bits (unless defined) are bypass bits for internal analog to digital interface pins with the same name. All the bits of this register, except the over-ride bits return a '0' on read, if VDDLDO is off.

5-1	SPARE_IN_CORE	R/W	0h	
0	PORZ	R	0h	Read only bit -andgt the PORZ generated from the digital registered on the A-D interface.

### 16.5.4.17 AD\_INTERFACE\_REG3 Register (offset = 4Ch) [reset = 0h]

AD\_INTERFACE\_REG3 is shown in Figure 16-150 and described in Table 16-161.

All bits (unless defined) are bypass bits for internal analog to digital interface pins with the same name. All the bits of this register, except the over-ride bits return a '0' on read, if VDDLDO is off.

**Figure 16-150. AD\_INTERFACE\_REG3 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-161. AD\_INTERFACE\_REG3 Register Field Descriptions**

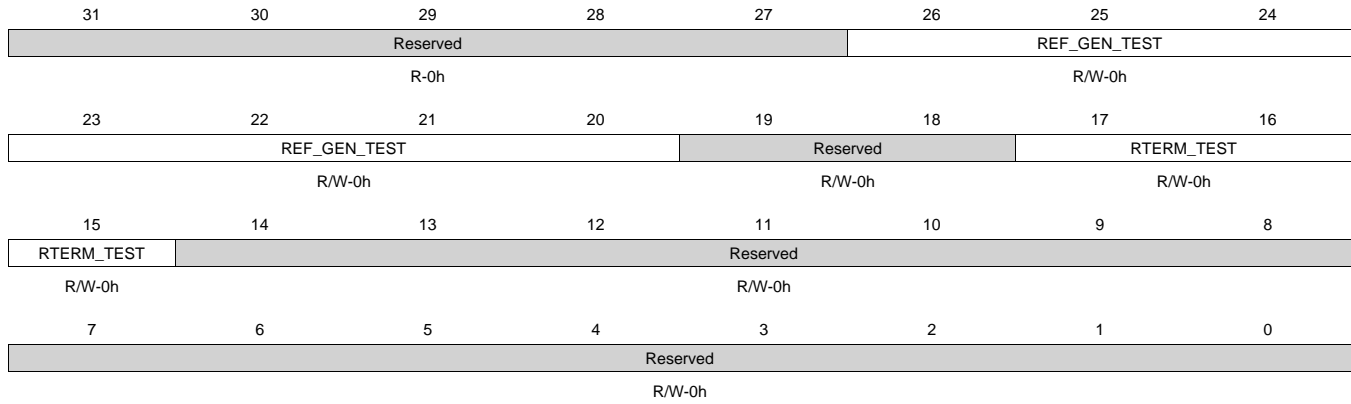

Bit	Field	Type	Reset	Description
31	USE_HSOS_DATA_REG	R/W	0h	Use bits 30-23 in this register as bypass bits
30-23	HSOS_DATA	R/W	0h	
22	USE_FS_REG3	R/W	0h	Use bits 20-21 as bypass bits
21	FSTX_MODE	R/W	0h	
20	FSTX_SE0	R/W	0h	
19	USE_HS_TERM_RES_REG	R/W	0h	Use bit 18 as override bit
18	HS_TERM_RES	R/W	0h	
17-10	SPARE_IN_LDO	R/W	0h	
9-2	SPARE_OUT_LDO	R	0h	
1	USE_FARCORE_REG	R/W	0h	Use bit 0 from this register as bypass
0	FARCORE	R/W	0h	

**16.5.4.18 ANA\_CONFIG2 Register (offset = 54h) [reset = 0h]**

ANA\_CONFIG2 is shown in [Figure 16-151](#) and described in [Table 16-162](#).

Used to configure and debug the analog blocks.

**Figure 16-151. ANA\_CONFIG2 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-162. ANA\_CONFIG2 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-27	Reserved	R	0h	Reserved.
26-20	REF_GEN_TEST	R/W	0h	0000000b - Produces the typical vertical eye diagram amplitude (default). 1100000b - Increases vertical eye diagram amplitude by 15 mV. 1010000b - Decreases vertical eye diagram amplitude by 15 mV. All other values are reserved.
19-18	Reserved	R/W	0h	Reserved.
17-15	RTERM_TEST	R/W	0h	000b - Typical termination impedance (default). 011b - Decreases the termination impedance by 2 to 3% and can be used to increase the vertical eye diagram amplitude by 1 to 1.5%. All other values reserved.
14-0	Reserved	R/W	0h	Reserved.

**16.5.5 CPPI\_DMA Registers**

[Table 16-163](#) lists the memory-mapped registers for the CPPI\_DMA. All register offset addresses not listed in [Table 16-163](#) should be considered as reserved locations and the register contents should not be modified.

**Table 16-163. CPPI\_DMA REGISTERS**

Offset	Acronym	Register Name	Section

### 16.5.5.1 DMAREVID Register (offset = 0h) [reset = 530901h]

DMAREVID is shown in [Figure 16-152](#) and described in [Table 16-164](#).

**Figure 16-152. DMAREVID Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

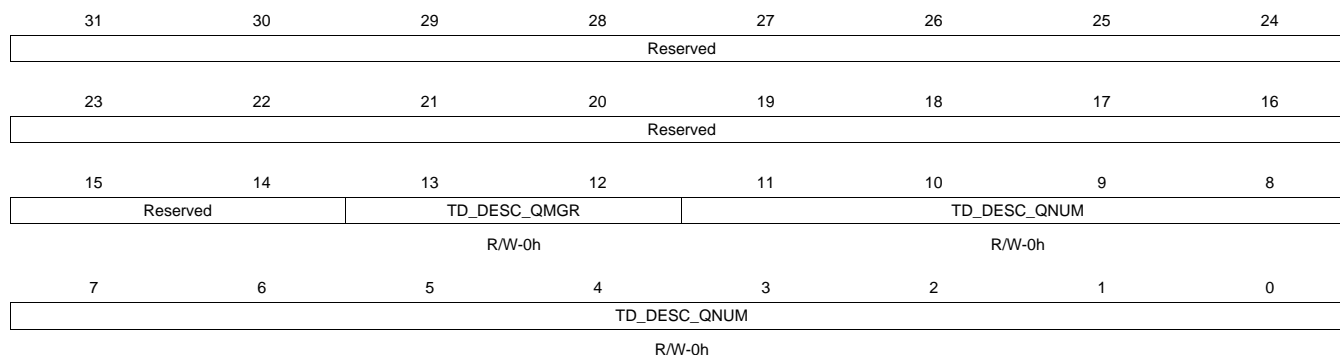

**Table 16-164. DMAREVID Register Field Descriptions**

Bit	Field	Type	Reset	Description
29-16	MODID	R-0	0	Module ID field
15-11	REVRTL	R-0	0	RTL revision. Will vary depending on release.
10-8	REVMAJ	R-0	0	Major revision.
7-0	REVMIN	R-0	0	Minor revision. CPPI DMA Revision Register

### 16.5.5.2 TDFDQ Register (offset = 4h) [reset = 0h]

TDFDQ is shown in [Figure 16-153](#) and described in [Table 16-165](#).

**Figure 16-153. TDFDQ Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-165. TDFDQ Register Field Descriptions**

Bit	Field	Type	Reset	Description
13-12	TD_DESC_QMGR	R/W	0h	This field controls which of the 4 Queue Managers the DMA will access in order to allocate a channel teardown descriptor from the teardown descriptor queue.
11-0	TD_DESC_QNUM	R/W	0h	This field controls which of the 2K queues in the indicated queue manager should be read in order to allocate channel teardown descriptors. CPPI DMA Teardown Free Descriptor Queue Control Register

### 16.5.5.3 DMAEMU Register (offset = 8h) [reset = 0h]

DMAEMU is shown in [Figure 16-154](#) and described in [Table 16-166](#).

0	FREE	R/W	0h	Enable for emulation suspend CPPI DMA Emulation Control Register

### 16.5.5.4 TXGCR0 Register (offset = 800h) [reset = 0h]

TXGCR0 is shown in [Figure 16-155](#) and described in [Table 16-167](#).

**Figure 16-155. TXGCR0 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-167. TXGCR0 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	TX_ENABLE	R/W	0h	This field enables or disables the channel 0 = channel is disabled 1 = channel is enabled This field will be cleared after a channel teardown is complete.
30	TX_TEARDOWN	R/W	0h	Setting this bit will request the channel to be torn down. This field will remain set after a channel teardown is complete.
13-12	TX_DEFAULT_QMGR	W	0h	This field controls the default queue manager number that will be used to queue teardown descriptors back to the host.
11-0	TX_DEFAULT_QNUM	W	0h	This field controls the default queue number within the selected queue manager onto which teardown descriptors will be queued back to the host. Table 98 -Tx Channel N Global Configuration Registers

### 16.5.5.5 RXGCR0 Register (offset = 808h) [reset = 0h]

RXGCR0 is shown in [Figure 16-156](#) and described in [Table 16-168](#).

**Figure 16-156. RXGCR0 Register**

31	30	29	28	27	26	25	24

7	6	5	4	3	2	1	0
RX_DEFAULT_RQ_QNUM							
W-0h							

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-168. RXGCR0 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	RX_ENABLE	R/W	0h	This field enables or disables the channel 0 = channel is disabled 1 = channel is enabled This field will be cleared after a channel teardown is complete.
30	RX_TEARDOWN	R/W	0h	This field indicates whether or not an Rx teardown operation is complete. This field should be cleared when a channel is initialized. This field will be set after a channel teardown is complete.
29	RX_PAUSE	R/W	0h	Setting this bit causes the CPPI DMA to be suspended for rx channels. If a pause is being requested and the channel is not in a packet then drop the credit.
24	RX_ERROR_HANDLING	W	0h	This bit controls the error handling mode for the channel and is only used when channel errors (i.e. descriptor or buffer starvation occurs): 0 = Starvation errors result in dropping packet and reclaiming any used descriptor or buffer resources back to the original queues/pools they were allocated to 1 = Starvation errors result in subsequent re-try of the descriptor allocation operation. In this mode, the DMA will return to the IDLE state without saving its internal operational state back to the internal state RAM and without issuing an advance operation on the FIFO interface. This results in the DMA re-initiating the FIFO block transfer at a later time with the intention that additional free buffers and/or descriptors will have been added. Regardless of the value of this bit, the DMA will assert the cdma_rx_sof_ overrun (for SOP) or cdma_rx_mof_ overrun (for non-SOP) when
23-16	RX_SOP_OFFSET	W	0h	This field specifies the number of bytes that are to be skipped in the SOP buffer before beginning to write the payload. This value must be less than the minimum size of a buffer in the system. Valid values are 0 - 255 bytes.

**Table 16-168. RXGCR0 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
15-14	RX_DEFAULT_DESC_TY PE	W	0h	This field indicates the default descriptor type to use: 0 = Reserved 1 = Host 2 = Reserved 3 = Reserved The actual descriptor type that will be used for reception can be overridden by information provided in the CPPI FIFO data block.
13-12	RX_DEFAULT_RQ_QMG R	W	0h	This field indicates the default receive queue manager that this channel should use. The actual receive queue manager index can be overridden by information provided in the CPPI FIFO data block.
11-0	RX_DEFAULT_RQ_QNU M	W	0h	This field indicates the default receive queue that this channel should use. The actual receive queue that will be used for reception can be overridden by information provided in the CPPI FIFO data block. Table 99 -Rx Channel N Global Configuration Registers

### 16.5.5.6 RXHPCRA0 Register (offset = 80Ch) [reset = 0h]

RXHPCRA0 is shown in [Figure 16-157](#) and described in [Table 16-169](#).

**Figure 16-157. RXHPCRA0 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-169. RXHPCRA0 Register Field Descriptions**

Bit	Field	Type	Reset	Description
29-28	RX_HOST_FDQ1_QMGR	W	0h	This field specifies which Buffer Manager should be used for the second Rx buffer in a host type packet.
27-16	RX_HOST_FDQ1_QNUM	W	0h	This field specifies which Free Descriptor / Buffer Pool should be used for the 2nd Rx buffer in a host type packet
13-12	RX_HOST_FDQ0_QMGR	W	0h	This field specifies which Buffer Manager should be used for the second Rx buffer in a host type packet.
11-0	RX_HOST_FDQ0_QNUM	W	0h	This field specifies which Free Descriptor / Buffer Pool should be used for the 1st Rx buffer in a host type packet Table 100 -Rx Channel N Host Packet Configuration Registers A

### 16.5.5.7 RXHPCR0 Register (offset = 810h) [reset = 0h]

RXHPCR0 is shown in [Figure 16-158](#) and described in [Table 16-170](#).

**Figure 16-158. RXHPCR0 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-170. RXHPCR0 Register Field Descriptions**

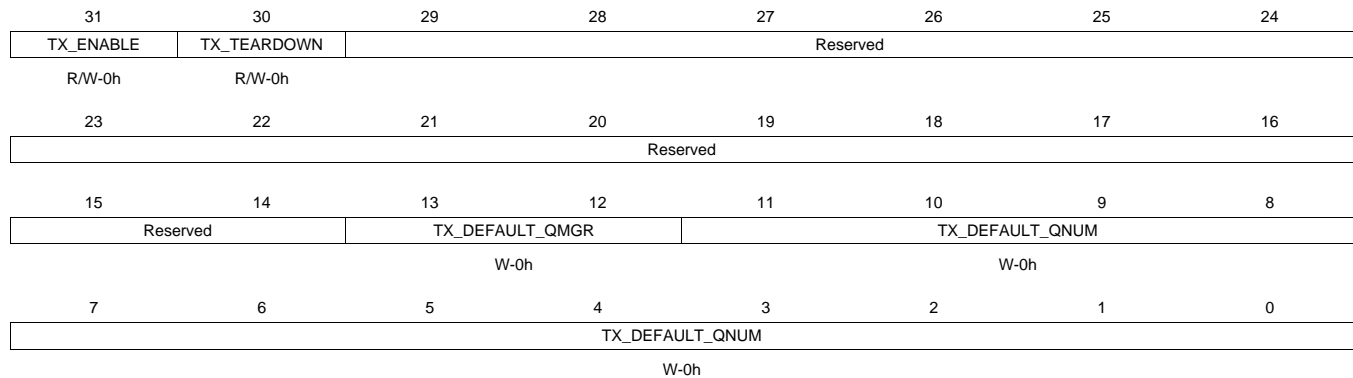

Bit	Field	Type	Reset	Description
29-28	RX_HOST_FDQ3_QMGR	W	0h	This field specifies which Manager should be used for the 4th or later Rx buffers in a host type packet
27-16	RX_HOST_FDQ3_QNUM	W	0h	This field specifies which Free Descriptor Queue should be used for the 4th or later Rx buffers in a host type packet
13-12	RX_HOST_FDQ2_QMGR	W	0h	This field specifies which Buffer Manager should be used for the 3rd Rx buffer in a host type packet
11-0	RX_HOST_FDQ2_QNUM	W	0h	This field specifies which Free Descriptor / Buffer Pool should be used for the 3rd Rx buffer in a host type packet Table 101 -Rx Channel N Host Packet Configuration Registers B

### 16.5.5.8 TXGCR1 Register (offset = 820h) [reset = 0h]

TXGCR1 is shown in [Figure 16-159](#) and described in [Table 16-171](#).

**Figure 16-159. TXGCR1 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-171. TXGCR1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	TX_ENABLE	R/W	0h	This field enables or disables the channel 0 = channel is disabled 1 = channel is enabled This field will be cleared after a channel teardown is complete.
30	TX_TEARDOWN	R/W	0h	Setting this bit will request the channel to be torn down. This field will remain set after a channel teardown is complete.
13-12	TX_DEFAULT_QMGR	W	0h	This field controls the default queue manager number that will be used to queue teardown descriptors back to the host.
11-0	TX_DEFAULT_QNUM	W	0h	This field controls the default queue number within the selected queue manager onto which teardown descriptors will be queued back to the host. Table 98 -Tx Channel N Global Configuration Registers

**16.5.5.9 RXGCR1 Register (offset = 828h) [reset = 0h]**

 RXGCR1 is shown in [Figure 16-160](#) and described in [Table 16-172](#).

**Table 16-172. RXGCR1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	RX_ENABLE	R/W	0h	This field enables or disables the channel 0 = channel is disabled 1 = channel is enabled This field will be cleared after a channel teardown is complete.
30	RX_TEARDOWN	R/W	0h	This field indicates whether or not an Rx teardown operation is complete. This field should be cleared when a channel is initialized. This field will be set after a channel teardown is complete.
29	RX_PAUSE	R/W	0h	Setting this bit causes the CPPI DMA to be suspended for rx channels. If a pause is being requested and the channel is not in a packet then drop the credit.
24	RX_ERROR_HANDLING	W	0h	This bit controls the error handling mode for the channel and is only used when channel errors (i.e. descriptor or buffer starvation occurs): 0 = Starvation errors result in dropping packet and reclaiming any used descriptor or buffer resources back to the original queues/pools they were allocated to 1 = Starvation errors result in subsequent re-try of the descriptor allocation operation. In this mode, the DMA will return to the IDLE state without saving its internal operational state back to the internal state RAM and without issuing an advance operation on the FIFO interface. This results in the DMA re-initiating the FIFO block transfer at a later time with the intention that additional free buffers and/or descriptors will have been added. Regardless of the value of this bit, the DMA will assert the cdma_rx_sof_overnrun (for SOP) or cdma_rx_mof_overnrun (for non-SOP) when
23-16	RX_SOP_OFFSET	W	0h	This field specifies the number of bytes that are to be skipped in the SOP buffer before beginning to write the payload. This value must be less than the minimum size of a buffer in the system. Valid values are 0 - 255 bytes.

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-188. RXGCR5 Register Field Descriptions**

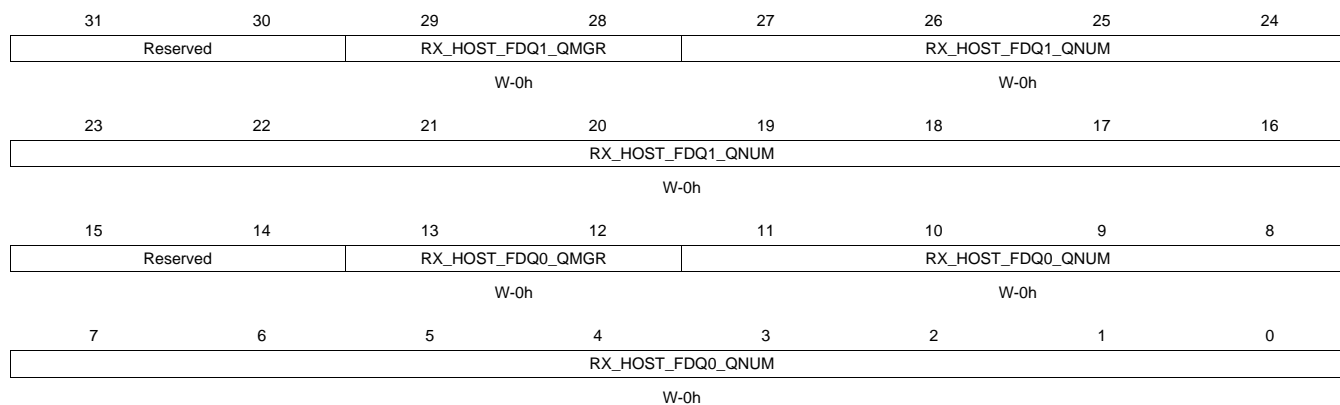

Bit	Field	Type	Reset	Description
31	RX_ENABLE	R/W	0h	This field enables or disables the channel 0 = channel is disabled 1 = channel is enabled This field will be cleared after a channel teardown is complete.
30	RX_TEARDOWN	R/W	0h	This field indicates whether or not an Rx teardown operation is complete. This field should be cleared when a channel is initialized. This field will be set after a channel teardown is complete.
29	RX_PAUSE	R/W	0h	Setting this bit causes the CPPI DMA to be suspended for rx channels. If a pause is being requested and the channel is not in a packet then drop the credit.
24	RX_ERROR_HANDLING	W	0h	This bit controls the error handling mode for the channel and is only used when channel errors (i.e. descriptor or buffer starvation occurs): 0 = Starvation errors result in dropping packet and reclaiming any used descriptor or buffer resources back to the original queues/pools they were allocated to 1 = Starvation errors result in subsequent re-try of the descriptor allocation operation. In this mode, the DMA will return to the IDLE state without saving its internal operational state back to the internal state RAM and without issuing an advance operation on the FIFO interface. This results in the DMA re-initiating the FIFO block transfer at a later time with the intention that additional free buffers and/or descriptors will have been added. Regardless of the value of this bit, the DMA will assert the cdma_rx_sof_ overrun (for SOP) or cdma_rx_mof_ overrun (for non-SOP) when
23-16	RX_SOP_OFFSET	W	0h	This field specifies the number of bytes that are to be skipped in the SOP buffer before beginning to write the payload. This value must be less than the minimum size of a buffer in the system. Valid values are 0 - 255 bytes.

**Table 16-188. RXGCR5 Register Field Descriptions (continued)**

TXGCR9 is shown in [Figure 16-191](#) and described in [Table 16-203](#).

**Figure 16-191. TXGCR9 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-203. TXGCR9 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	TX_ENABLE	R/W	0h	This field enables or disables the channel 0 = channel is disabled 1 = channel is enabled This field will be cleared after a channel teardown is complete.
30	TX_TEARDOWN	R/W	0h	Setting this bit will request the channel to be torn down. This field will remain set after a channel teardown is complete.
13-12	TX_DEFAULT_QMGR	W	0h	This field controls the default queue manager number that will be used to queue teardown descriptors back to the host.
11-0	TX_DEFAULT_QNUM	W	0h	This field controls the default queue number within the selected queue manager onto which teardown descriptors will be queued back to the host. Table 98 -Tx Channel N Global Configuration Registers

**16.5.5.41 RXGCR9 Register (offset = 928h) [reset = 0h]**

 RXGCR9 is shown in [Figure 16-192](#) and described in [Table 16-204](#).

**Figure 16-192. RXGCR9 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-204. RXGCR9 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	RX_ENABLE	R/W	0h	This field enables or disables the channel 0 = channel is disabled 1 = channel is enabled This field will be cleared after a channel teardown is complete.
30	RX_TEARDOWN	R/W	0h	This field indicates whether or not an Rx teardown operation is complete. This field should be cleared when a channel is initialized. This field will be set after a channel teardown is complete.
29	RX_PAUSE	R/W	0h	Setting this bit causes the CPPI DMA to be suspended for rx channels. If a pause is being requested and the channel is not in a packet then drop the credit.
24	RX_ERROR_HANDLING	W	0h	This bit controls the error handling mode for the channel and is only used when channel errors (i.e. descriptor or buffer starvation occurs): 0 = Starvation errors result in dropping packet and reclaiming any used descriptor or buffer resources back to the original queues/pools they were allocated to 1 = Starvation errors result in subsequent re-try of the descriptor allocation operation. In this mode, the DMA will return to the IDLE state without saving it's internal operational state back to the internal state RAM and without issuing an advance operation on the FIFO interface. This results in the DMA re-initiating the FIFO block transfer at a later time with the intention that additional free buffers and/or descriptors will have been added. Regardless of the value of this bit, the DMA will assert the cdma_rx_sof_overrun (for SOP) or cdma_rx_mof_overrun (for non-SOP) when
23-16	RX_SOP_OFFSET	W	0h	This field specifies the number of bytes that are to be skipped in the SOP buffer before beginning to write the payload. This value must be less than the minimum size of a buffer in the system. Valid values are 0 - 255 bytes.

**Table 16-204. RXGCR9 Register Field Descriptions (continued)**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-236. RXGCR17 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	RX_ENABLE	R/W	0h	This field enables or disables the channel 0 = channel is disabled 1 = channel is enabled This field will be cleared after a channel teardown is complete.
30	RX_TEARDOWN	R/W	0h	This field indicates whether or not an Rx teardown operation is complete. This field should be cleared when a channel is initialized. This field will be set after a channel teardown is complete.
29	RX_PAUSE	R/W	0h	Setting this bit causes the CPPI DMA to be suspended for rx channels. If a pause is being requested and the channel is not in a packet then drop the credit.
24	RX_ERROR_HANDLING	W	0h	This bit controls the error handling mode for the channel and is only used when channel errors (i.e. descriptor or buffer starvation occurs): 0 = Starvation errors result in dropping packet and reclaiming any used descriptor or buffer resources back to the original queues/pools they were allocated to 1 = Starvation errors result in subsequent re-try of the descriptor allocation operation. In this mode, the DMA will return to the IDLE state without saving its internal operational state back to the internal state RAM and without issuing an advance operation on the FIFO interface. This results in the DMA re-initiating the FIFO block transfer at a later time with the intention that additional free buffers and/or descriptors will have been added. Regardless of the value of this bit, the DMA will assert the cdma_rx_sof_ overrun (for SOP) or cdma_rx_mof_ overrun (for non-SOP) when
23-16	RX_SOP_OFFSET	W	0h	This field specifies the number of bytes that are to be skipped in the SOP buffer before beginning to write the payload. This value must be less than the minimum size of a buffer in the system. Valid values are 0 - 255 bytes.

30	RX_TEARDOWN	R/W	0h	This field indicates whether or not an Rx teardown operation is complete. This field should be cleared when a channel is initialized. This field will be set after a channel teardown is complete.
29	RX_PAUSE	R/W	0h	Setting this bit causes the CPPI DMA to be suspended for rx channels. If a pause is being requested and the channel is not in a packet then drop the credit.
24	RX_ERROR_HANDLING	W	0h	This bit controls the error handling mode for the channel and is only used when channel errors (i.e. descriptor or buffer starvation occurs): 0 = Starvation errors result in dropping packet and reclaiming any used descriptor or buffer resources back to the original queues/pools they were allocated to 1 = Starvation errors result in subsequent re-try of the descriptor allocation operation. In this mode, the DMA will return to the IDLE state without saving its internal operational state back to the internal state RAM and without issuing an advance operation on the FIFO interface. This results in the DMA re-initiating the FIFO block transfer at a later time with the intention that additional free buffers and/or descriptors will have been added. Regardless of the value of this bit, the DMA will assert the cdma_rx_sof_ overrun (for SOP) or cdma_rx_mof_ overrun (for non-SOP) when
23-16	RX_SOP_OFFSET	W	0h	This field specifies the number of bytes that are to be skipped in the SOP buffer before beginning to write the payload. This value must be less than the minimum size of a buffer in the system. Valid values are 0 - 255 bytes.

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-280. RXGCR28 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	RX_ENABLE	R/W	0h	This field enables or disables the channel 0 = channel is disabled 1 = channel is enabled This field will be cleared after a channel teardown is complete.
30	RX_TEARDOWN	R/W	0h	This field indicates whether or not an Rx teardown operation is complete. This field should be cleared when a channel is initialized. This field will be set after a channel teardown is complete.
29	RX_PAUSE	R/W	0h	Setting this bit causes the CPPI DMA to be suspended for rx channels. If a pause is being requested and the channel is not in a packet then drop the credit.
24	RX_ERROR_HANDLING	W	0h	This bit controls the error handling mode for the channel and is only used when channel errors (i.e. descriptor or buffer starvation occurs): 0 = Starvation errors result in dropping packet and reclaiming any used descriptor or buffer resources back to the original queues/pools they were allocated to 1 = Starvation errors result in subsequent re-try of the descriptor allocation operation. In this mode, the DMA will return to the IDLE state without saving its internal operational state back to the internal state RAM and without issuing an advance operation on the FIFO interface. This results in the DMA re-initiating the FIFO block transfer at a later time with the intention that additional free buffers and/or descriptors will have been added. Regardless of the value of this bit, the DMA will assert the cdma_rx_sof_overnrun (for SOP) or cdma_rx_mof_overnrun (for non-SOP) when
23-16	RX_SOP_OFFSET	W	0h	This field specifies the number of bytes that are to be skipped in the SOP buffer before beginning to write the payload. This value must be less than the minimum size of a buffer in the system. Valid values are 0 - 255 bytes.

**Table 16-280. RXGCR28 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
15-14	RX_DEFAULT_DESC_TY PE	W	0h	This field indicates the default descriptor type to use: 0 = Reserved 1 = Host 2 = Reserved 3 = Reserved The actual descriptor type that will be used for reception can be overridden by information provided in the CPPI FIFO data block.
13-12	RX_DEFAULT_RQ_QMG R	W	0h	This field indicates the default receive queue manager that this channel should use. The actual receive queue manager index can be overridden by information provided in the CPPI FIFO data block.
11-0	RX_DEFAULT_RQ_QNU M	W	0h	This field indicates the default receive queue that this channel should use. The actual receive queue that will be used for reception can be overridden by information provided in the CPPI FIFO data block. Table 99 -Rx Channel N Global Configuration Registers

### 16.5.6 CPPI\_DMA\_SCHEDULER Registers

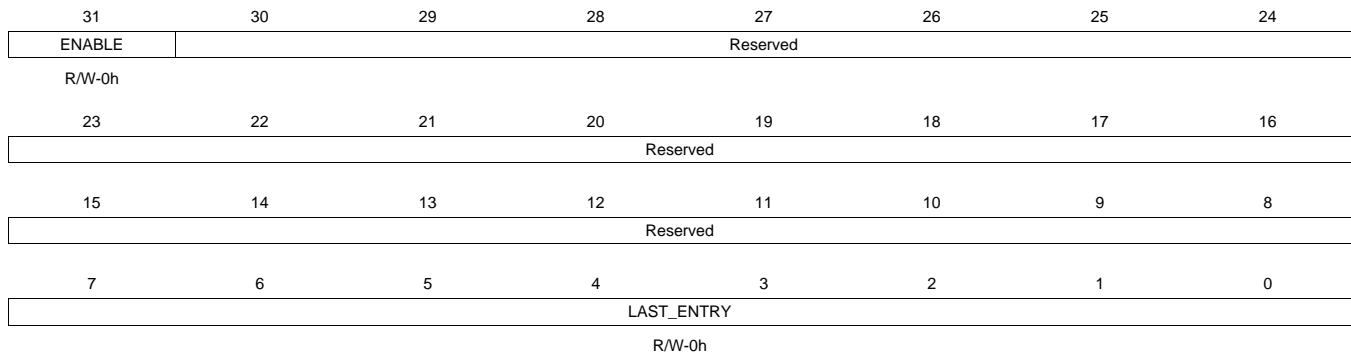

[Table 16-287](#) lists the memory-mapped registers for the CPPI\_DMA\_SCHEDULER. All register offset addresses not listed in [Table 16-287](#) should be considered as reserved locations and the register contents should not be modified.

**Table 16-287. CPPI\_DMA\_SCHEDULER REGISTERS**

Offset	Acronym	Register Name	Section
0h	DMA_SCHED_CTRL		<a href="#">Section 16.5.6.1</a>
800h to 900h	WORD0 to WORD63		<a href="#">Section 16.5.6.2</a>

**16.5.6.1 DMA\_SCHED\_CTRL Register (offset = 0h) [reset = 0h]**

 DMA\_SCHED\_CTRL is shown in [Figure 16-275](#) and described in [Table 16-288](#).

**Figure 16-275. DMA\_SCHED\_CTRL Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-288. DMA\_SCHED\_CTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	ENABLE	R/W	0h	This is the enable bit for the scheduler and is encoded as follows: 0 = scheduler is disabled and will no longer fetch entries from the scheduler table or pass credits to the DMA controller 1 = scheduler is enabled This bit should only be set after the table has been initialized.
7-0	LAST_ENTRY	R/W	0h	This field indicates the last valid entry in the scheduler table. There are 64 words in the table and there are 4 entries in each word. The table can be programmed with any integer number of entries from 1 to 256. The corresponding encoding for this field is as follows: 0 = 1 entry 1 = 2 entries ... 254 = 255 entries 255 = 256 entries CPPI DMA Scheduler Control Registers

### 16.5.6.2 WORDx Register (offset = 800h to 900h) [reset = 0h]

WORD0 to WORD63 is shown in [Figure 16-276](#) and described in [Table 16-289](#).

**Figure 16-276. WORD0 to WORD63 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-289. WORD0 to WORD63 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	ENTRY3_RXTX	W	0h	This bit indicates if this entry is for a Tx or an Rx channel and is encoded as follows: 0 = Tx Channel 1 = Rx Channel
28-24	ENTRY3_CHANNEL	R/W		This field indicates the channel number that is to be given an opportunity to transfer data. If this is a Tx entry, the DMA will be presented with a scheduling credit for that exact Tx channel. If this is an Rx entry, the DMA will be presented with a scheduling credit for the Rx FIFO that is associated with this channel. For Rx FIFOs which carry traffic for more than 1 Rx DMA channel, the exact channel number that is given in the Rx credit will actually be the channel number which is currently on the head element of that Rx FIFO, which is not necessarily the channel number given in the scheduler table entry.
23	ENTRY2_RXTX	W	0h	This bit indicates if this entry is for a Tx or an Rx channel and is encoded as follows: 0 = Tx Channel 1 = Rx Channel
20-16	ENTRY2_CHANNEL	R/W		This field indicates the channel number that is to be given an opportunity to transfer data. If this is a Tx entry, the DMA will be presented with a scheduling credit for that exact Tx channel. If this is an Rx entry, the DMA will be presented with a scheduling credit for the Rx FIFO that is associated with this channel. For Rx FIFOs which carry traffic for more than 1 Rx DMA channel, the exact channel number that is given in the Rx credit will actually be the channel number which is currently on the head element of that Rx FIFO, which is not necessarily the channel number given in the scheduler table entry.
15	ENTRY1_RXTX	W	0h	This bit indicates if this entry is for a Tx or an Rx channel and is encoded as follows: 0 = Tx Channel 1 = Rx Channel

**Table 16-289. WORD0 to WORD63 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
12-8	ENTRY1_CHANNEL	R/W		This field indicates the channel number that is to be given an opportunity to transfer data. If this is a Tx entry, the DMA will be presented with a scheduling credit for that exact Tx channel. If this is an Rx entry, the DMA will be presented with a scheduling credit for the Rx FIFO that is associated with this channel. For Rx FIFOs which carry traffic for more than 1 Rx DMA channel, the exact channel number that is given in the Rx credit will actually be the channel number which is currently on the head element of that Rx FIFO, which is not necessarily the channel number given in the scheduler table entry.
7	ENTRY0_RXTX	W	0h	This bit indicates if this entry is for a Tx or an Rx channel and is encoded as follows: 0 = Tx Channel 1 = Rx Channel
4-0	ENTRY0_CHANNEL	R/W		This field indicates the channel number that is to be given an opportunity to transfer data. If this is a Tx entry, the DMA will be presented with a scheduling credit for that exact Tx channel. If this is an Rx entry, the DMA will be presented with a scheduling credit for the Rx FIFO that is associated with this channel. For Rx FIFOs which carry traffic for more than 1 Rx DMA channel, the exact channel number that is given in the Rx credit will actually be the channel number which is currently on the head element of that Rx FIFO, which is not necessarily the channel number given in the scheduler table entry.

### 16.5.7 QUEUE\_MGR Registers

Table 16-290 lists the memory-mapped registers for the QUEUE\_MGR. All register offset addresses not listed in Table 16-290 should be considered as reserved locations and the register contents should not be modified.

### 16.5.7.1 QMGRREVID Register (offset = 0h) [reset = 4E530800h]

QMGRREVID is shown in [Figure 16-277](#) and described in [Table 16-291](#).

**Figure 16-277. QMGRREVID Register**

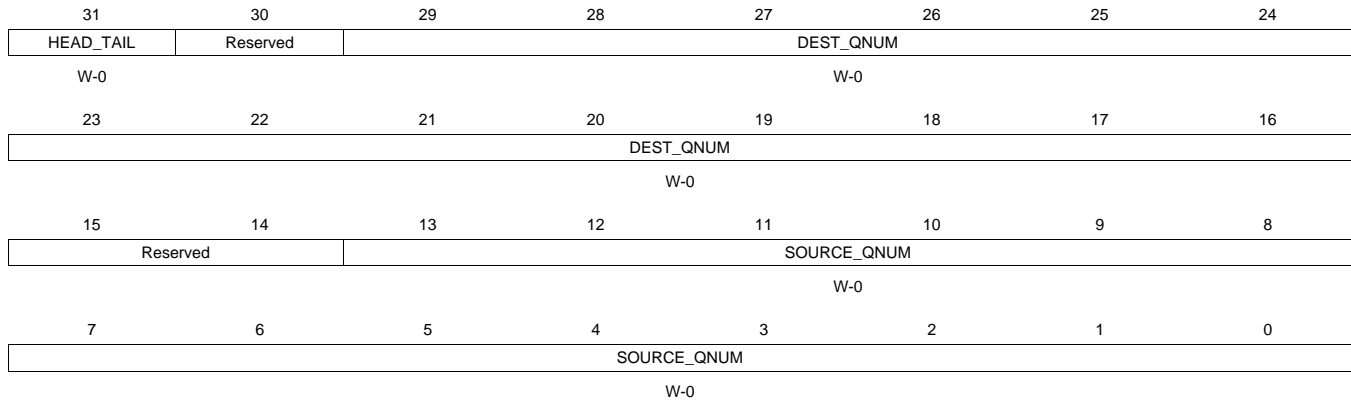

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-291. QMGRREVID Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-30	SCHEME	R-0	0	Scheme that this register is compliant with
27-16	FUNCTION	R-0	0	Function
15-11	REVRTL	R-0	0	RTL revision
10-8	REVMAJ	R-0	0	Major revision
7-6	REVCUSTOM	R-0	0	Custom revision
5-0	REVMIN	R-0	0	Minor revision Queue Manager Revision Register

**16.5.7.2 QMGRST Register (offset = 8h) [reset = 0h]**

 QMGRST is shown in [Figure 16-278](#) and described in [Table 16-292](#).

**Figure 16-278. QMGRST Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

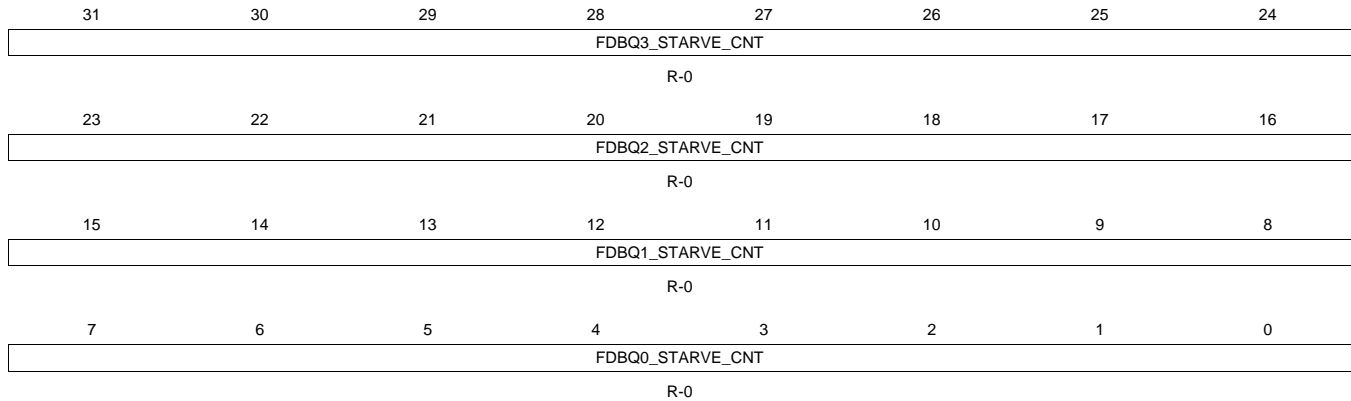

**Table 16-292. QMGRST Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	HEAD_TAIL	W-0	0	Indicates whether queue contents should be merged on to head or tail of destination queue. Clear this field for head and set for tail.
29-16	DEST_QNUM	W-0	0	Destination Queue Number
13-0	SOURCE_QNUM	W-0	0	Source Queue Number Queue Manager Queue Diversion Register Note : CBA write transactions to this register cause the QMGR to start processing an internal state machine. This disables CBA read transactions while it is busy processing the state machine. Once the state machine is back in the idle state CBA read transactions are available again.

### 16.5.7.3 FDBSC0 Register (offset = 20h) [reset = 0h]

FDBSC0 is shown in [Figure 16-279](#) and described in [Table 16-293](#).

**Figure 16-279. FDBSC0 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

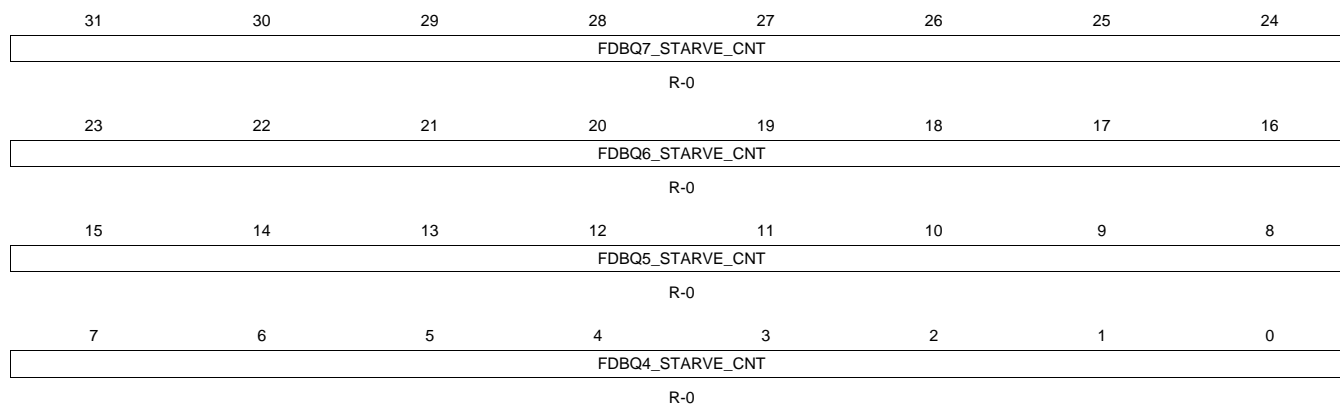

**Table 16-293. FDBSC0 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	FDBQ3_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 3 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu.
23-16	FDBQ2_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 2 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu.
15-8	FDBQ1_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 1 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu.
7-0	FDBQ0_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 0 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu. Queue_Manager_Free_Descriptor_Buffer_Starvation_Count Register 0

### 16.5.7.4 FDBSC1 Register (offset = 24h) [reset = 0h]

FDBSC1 is shown in [Figure 16-280](#) and described in [Table 16-294](#).

**Figure 16-280. FDBSC1 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-294. FDBSC1 Register Field Descriptions**

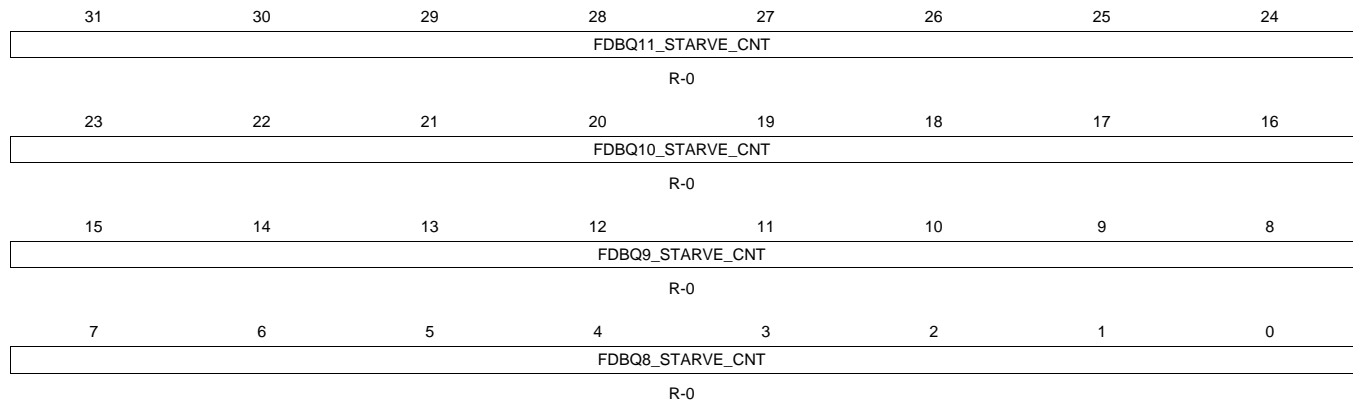

Bit	Field	Type	Reset	Description
31-24	FDBQ7_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 7 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu.
23-16	FDBQ6_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 6 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu.
15-8	FDBQ5_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 5 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu.
7-0	FDBQ4_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 4 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu. Queue_Manager_Free_Descriptor_Buffer_Starvation_Count Register 1

### 16.5.7.5 FDBSC2 Register (offset = 28h) [reset = 0h]

FDBSC2 is shown in [Figure 16-281](#) and described in [Table 16-295](#).

**Figure 16-281. FDBSC2 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

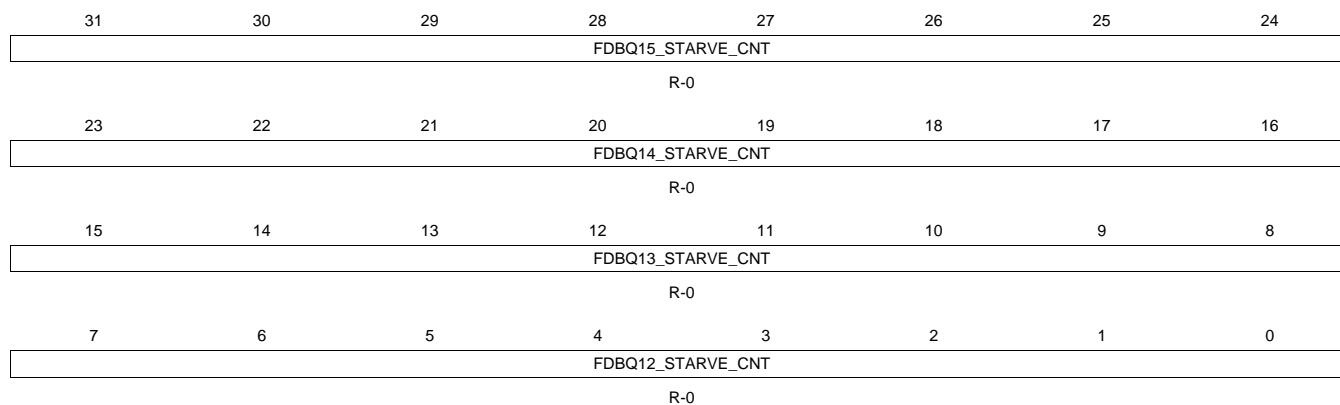

**Table 16-295. FDBSC2 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	FDBQ11_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 11 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu.
23-16	FDBQ10_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 10 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu.
15-8	FDBQ9_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 9 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu.
7-0	FDBQ8_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 8 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu. Queue_Manager_Free_Descriptor_Buffer_Starvation_Count Register 2

### 16.5.7.6 FDBSC3 Register (offset = 2Ch) [reset = 0h]

FDBSC3 is shown in [Figure 16-282](#) and described in [Table 16-296](#).

**Figure 16-282. FDBSC3 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

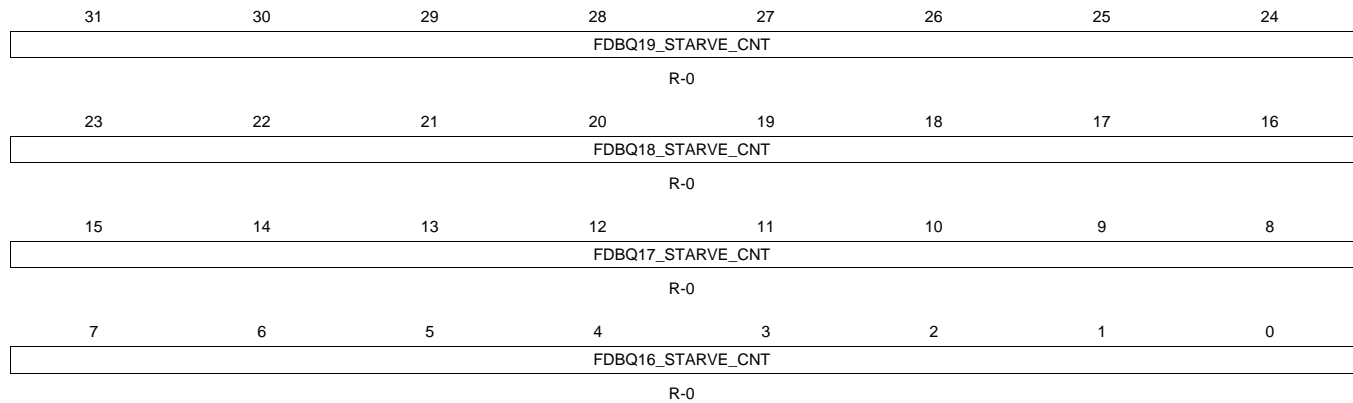

**Table 16-296. FDBSC3 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	FDBQ15_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 15 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu.
23-16	FDBQ14_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 14 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu.
15-8	FDBQ13_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 13 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu.
7-0	FDBQ12_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 12 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu. Table 109 - QMGR_Free_Descriptor_Buffer_Starvation_Count Register 3

### 16.5.7.7 FDBSC4 Register (offset = 30h) [reset = 0h]

FDBSC4 is shown in [Figure 16-283](#) and described in [Table 16-297](#).

**Figure 16-283. FDBSC4 Register**

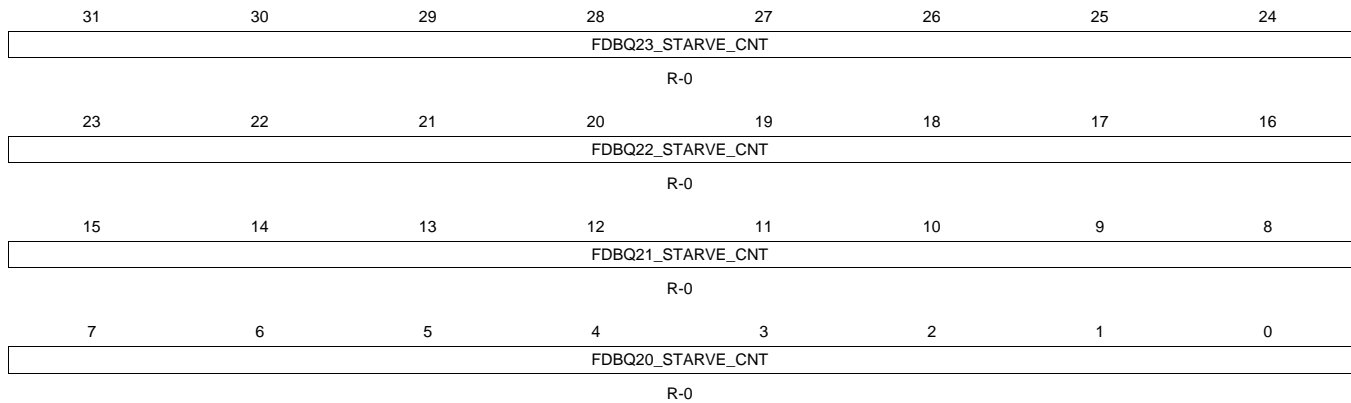

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-297. FDBSC4 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	FDBQ19_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 19 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu.
23-16	FDBQ18_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 18 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu.
15-8	FDBQ17_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 17 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu.
7-0	FDBQ16_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 16 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu. Queue_Manager_Free_Descriptor_Buffer_Starvation_Count Register 4

**16.5.7.8 FDBSC5 Register (offset = 34h) [reset = 0h]**

 FDBSC5 is shown in [Figure 16-284](#) and described in [Table 16-298](#).

**Figure 16-284. FDBSC5 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

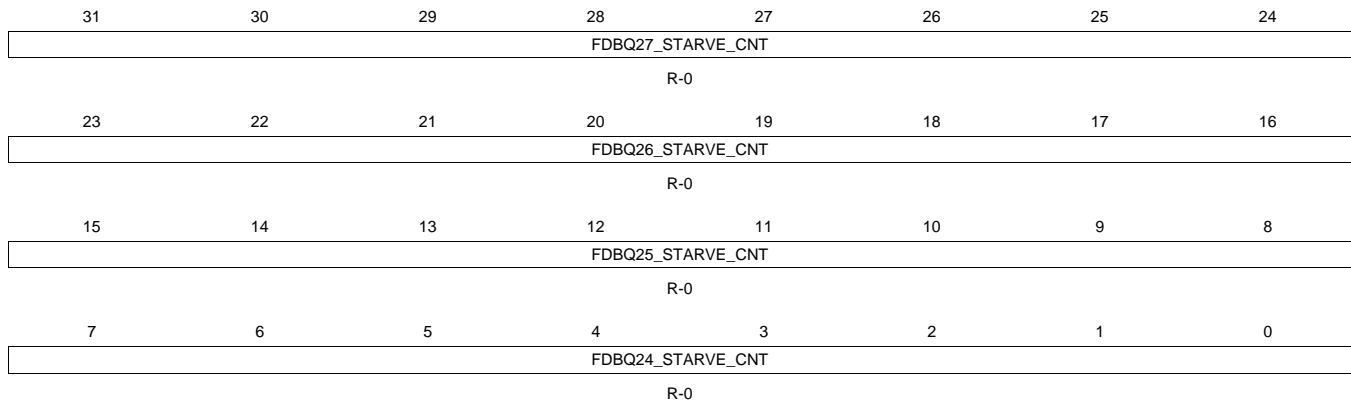

**Table 16-298. FDBSC5 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	FDBQ23_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 23 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu.
23-16	FDBQ22_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 22 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu.
15-8	FDBQ21_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 21 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu.
7-0	FDBQ20_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 20 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu. Queue_Manager_Free_Descriptor_Buffer_Starvation_Count Register 5

### 16.5.7.9 FDBSC6 Register (offset = 38h) [reset = 0h]

FDBSC6 is shown in [Figure 16-285](#) and described in [Table 16-299](#).

**Figure 16-285. FDBSC6 Register**

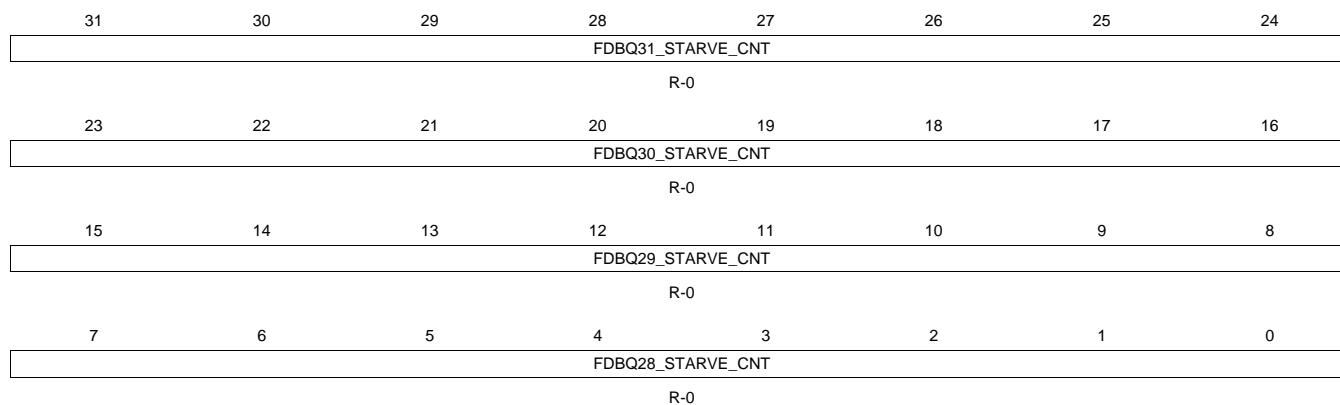

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-299. FDBSC6 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	FDBQ27_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 27 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu.
23-16	FDBQ26_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 26 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu.
15-8	FDBQ25_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 25 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu.
7-0	FDBQ24_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 24 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu. Queue_Manager_Free_Descriptor_Buffer_Starvation_Count Register 6

**16.5.7.10 FDBSC7 Register (offset = 3Ch) [reset = 0h]**

 FDBSC7 is shown in [Figure 16-286](#) and described in [Table 16-300](#).

**Figure 16-286. FDBSC7 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-300. FDBSC7 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	FDBQ31_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 31 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu.
23-16	FDBQ30_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 30 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu.
15-8	FDBQ29_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 29 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu.
7-0	FDBQ28_STARVE_CNT	R-0	0	This field increments each time the Free Descriptor/Buffer Queue 28 is read while it is empty via the CPPI DMA. This field is cleared when read via the cpu. Queue_Manager_Free_Descriptor_Buffer_Starvation_Count Register 7

### 16.5.7.11 LRAM0BASE Register (offset = 80h) [reset = 0h]

LRAM0BASE is shown in [Figure 16-287](#) and described in [Table 16-301](#).

**Figure 16-287. LRAM0BASE Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-301. LRAM0BASE Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	REGION0_BASE	R/W-0	0	This field stores the base address for the first region of the linking RAM. This may be anywhere in 32-bit address space but would be typically located in on-chip memory.

**16.5.7.12 LRAM0SIZE Register (offset = 84h) [reset = 0h]**

LRAM0SIZE is shown in [Figure 16-288](#) and described in [Table 16-302](#).

**Figure 16-288. LRAM0SIZE Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-302. LRAM0SIZE Register Field Descriptions**

Bit	Field	Type	Reset	Description
13-0	REGION0_SIZE	R/W-0	0	This field indicates the number of entries that are contained in the linking RAM region 0. A descriptor with index less than region0_size value has its linking location in region 0. A descriptor with index greater than region0_size has its linking location in region 1. The queue manager will add the index (left shifted by 2 bits) to the appropriate regionX_base_addr to get the absolute 32-bit address to the linking location for a descriptor. Queue Manager Linking Ram Region 0 Size Register

### 16.5.7.13 LRAM1BASE Register (offset = 88h) [reset = 0h]

LRAM1BASE is shown in [Figure 16-289](#) and described in [Table 16-303](#).

**Figure 16-289. LRAM1BASE Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-303. LRAM1BASE Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	REGION1_BASE	R/W-0	0	This field stores the base address for the second region of the linking RAM. This may be anywhere in 32-bit address space but would be typically located in off-chip memory.

**16.5.7.14 PEND0 Register (offset = 90h) [reset = 0h]**

PEND0 is shown in [Figure 16-290](#) and described in [Table 16-304](#).

**Figure 16-290. PEND0 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-304. PEND0 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	QPEND0	R-0	0	This field indicates the queue pending status for queues[31:0].

### 16.5.7.15 PEND1 Register (offset = 94h) [reset = 0h]

PEND1 is shown in [Figure 16-291](#) and described in [Table 16-305](#).

**Figure 16-291. PEND1 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-305. PEND1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	QPEND1	R-0	0	This field indicates the queue pending status for queues[63:32]. Table 118 - QMGR_Queue_Pending_1 Register 1

**16.5.7.16 PEND2 Register (offset = 98h) [reset = 0h]**

PEND2 is shown in [Figure 16-292](#) and described in [Table 16-306](#).

**Figure 16-292. PEND2 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-306. PEND2 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	QPEND2	R-0	0	This field indicates the queue pending status for queues[95:64]. Queue_Manager_Queue_Pending_2 Register 2

**16.5.7.17 PEND3 Register (offset = 9Ch) [reset = 0h]**

PEND3 is shown in [Figure 16-293](#) and described in [Table 16-307](#).

**Figure 16-293. PEND3 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-307. PEND3 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	QPEND3	R-0	0	This field indicates the queue pending status for queues[127:96]. Queue_Manager_Queue_Pending_3 Register 3

**16.5.7.18 PEND4 Register (offset = A0h) [reset = 0h]**

PEND4 is shown in [Figure 16-294](#) and described in [Table 16-308](#).

**Figure 16-294. PEND4 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-308. PEND4 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	QPEND4	R-0	0	This field indicates the queue pending status for queues[159:128]. Queue_Manager_Queue_Pending_4 Register 4

### 16.5.7.19 QMEMRBASE0 Register (offset = 1000h) [reset = 0h]

QMEMRBASE0 is shown in [Figure 16-295](#) and described in [Table 16-309](#).

**Figure 16-295. QMEMRBASE0 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-309. QMEMRBASE0 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-5	REG	R/W-0	0	This field contains the base address of the memory region R.

**16.5.7.20 QMEMCTRL0 Register (offset = 1004h) [reset = 0h]**

 QMEMCTRL0 is shown in [Figure 16-296](#) and described in [Table 16-310](#).

**Figure 16-296. QMEMCTRL0 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-310. QMEMCTRL0 Register Field Descriptions**

Bit	Field	Type	Reset	Description
29-16	START_INDEX	R/W-0	0	This field indicates where in linking RAM does the descriptor linking information corresponding to memory region R starts.
11-8	DESC_SIZE	R/W-0	0	This field indicates the size of each descriptor in this memory region. It is an encoded value that specifies descriptor size as $2^{(5+desc\_size)}$ number of bytes. The settings of desc_size from 9-15 are reserved.
2-0	REG_SIZE	R/W-0	0	This field indicates the size of the memory region (in terms of number of descriptors). It is an encoded value that specifies region size as $2^{(5+reg\_size)}$ number of descriptors. Queue Manager Memory Region R Control Registers The following sections describe each of the four register locations that may be present for each queue in the queues region. For reasons of implementation and area efficiency, these registers are not actually implemented as a huge array of flip flops but are instead implemented as a single set of mailbox registers which use the LSBs of the provided address as a queue index. Due to this implementation all accesses to these registers need to be performed as a single burst write for each packet push operation or a single burst read for each packet pop operation. The length of a burst to push or pop a packet will vary depending on the optional features that the queue supports which may be 4, 8, 12 or 16 bytes. Queue N Register D must always be written / read in the burst but the preceding words are optional depending on the required queue functionality.

### 16.5.7.21 QMEMRBASE1 Register (offset = 1010h) [reset = 0h]

QMEMRBASE1 is shown in [Figure 16-297](#) and described in [Table 16-311](#).

**Figure 16-297. QMEMRBASE1 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-311. QMEMRBASE1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-5	REG	R/W-0	0	This field contains the base address of the memory region R.

**16.5.7.22 QMEMCTRL1 Register (offset = 1014h) [reset = 0h]**

 QMEMCTRL1 is shown in [Figure 16-298](#) and described in [Table 16-312](#).

**Figure 16-298. QMEMCTRL1 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-312. QMEMCTRL1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
29-16	START_INDEX	R/W-0	0	This field indicates where in linking RAM does the descriptor linking information corresponding to memory region R starts.
11-8	DESC_SIZE	R/W-0	0	This field indicates the size of each descriptor in this memory region. It is an encoded value that specifies descriptor size as $2^{(5+desc\_size)}$ number of bytes. The settings of desc_size from 9-15 are reserved.
2-0	REG_SIZE	R/W-0	0	This field indicates the size of the memory region (in terms of number of descriptors). It is an encoded value that specifies region size as $2^{(5+reg\_size)}$ number of descriptors. Queue Manager Memory Region R Control Registers The following sections describe each of the four register locations that may be present for each queue in the queues region. For reasons of implementation and area efficiency, these registers are not actually implemented as a huge array of flip flops but are instead implemented as a single set of mailbox registers which use the LSBs of the provided address as a queue index. Due to this implementation all accesses to these registers need to be performed as a single burst write for each packet push operation or a single burst read for each packet pop operation. The length of a burst to push or pop a packet will vary depending on the optional features that the queue supports which may be 4, 8, 12 or 16 bytes. Queue N Register D must always be written / read in the burst but the preceding words are optional depending on the required queue functionality.

### 16.5.7.23 QMEMRBASE2 Register (offset = 1020h) [reset = 0h]

QMEMRBASE2 is shown in [Figure 16-299](#) and described in [Table 16-313](#).

**Figure 16-299. QMEMRBASE2 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-313. QMEMRBASE2 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-5	REG	R/W-0	0	This field contains the base address of the memory region R.

**16.5.7.24 QMEMCTRL2 Register (offset = 1024h) [reset = 0h]**

 QMEMCTRL2 is shown in [Figure 16-300](#) and described in [Table 16-314](#).

**Figure 16-300. QMEMCTRL2 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-314. QMEMCTRL2 Register Field Descriptions**

Bit	Field	Type	Reset	Description
29-16	START_INDEX	R/W-0	0	This field indicates where in linking RAM does the descriptor linking information corresponding to memory region R starts.
11-8	DESC_SIZE	R/W-0	0	This field indicates the size of each descriptor in this memory region. It is an encoded value that specifies descriptor size as $2^{(5+desc\_size)}$ number of bytes. The settings of desc_size from 9-15 are reserved.
2-0	REG_SIZE	R/W-0	0	This field indicates the size of the memory region (in terms of number of descriptors). It is an encoded value that specifies region size as $2^{(5+reg\_size)}$ number of descriptors. Queue Manager Memory Region R Control Registers The following sections describe each of the four register locations that may be present for each queue in the queues region. For reasons of implementation and area efficiency, these registers are not actually implemented as a huge array of flip flops but are instead implemented as a single set of mailbox registers which use the LSBs of the provided address as a queue index. Due to this implementation all accesses to these registers need to be performed as a single burst write for each packet push operation or a single burst read for each packet pop operation. The length of a burst to push or pop a packet will vary depending on the optional features that the queue supports which may be 4, 8, 12 or 16 bytes. Queue N Register D must always be written / read in the burst but the preceding words are optional depending on the required queue functionality.

### 16.5.7.25 QMEMRBASE3 Register (offset = 1030h) [reset = 0h]

QMEMRBASE3 is shown in [Figure 16-301](#) and described in [Table 16-315](#).

**Figure 16-301. QMEMRBASE3 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-315. QMEMRBASE3 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-5	REG	R/W-0	0	This field contains the base address of the memory region R.

**16.5.7.26 QMEMCTRL3 Register (offset = 1034h) [reset = 0h]**

 QMEMCTRL3 is shown in [Figure 16-302](#) and described in [Table 16-316](#).

**Figure 16-302. QMEMCTRL3 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-316. QMEMCTRL3 Register Field Descriptions**

Bit	Field	Type	Reset	Description
29-16	START_INDEX	R/W-0	0	This field indicates where in linking RAM does the descriptor linking information corresponding to memory region R starts.
11-8	DESC_SIZE	R/W-0	0	This field indicates the size of each descriptor in this memory region. It is an encoded value that specifies descriptor size as $2^{(5+desc\_size)}$ number of bytes. The settings of desc_size from 9-15 are reserved.
2-0	REG_SIZE	R/W-0	0	This field indicates the size of the memory region (in terms of number of descriptors). It is an encoded value that specifies region size as $2^{(5+reg\_size)}$ number of descriptors. Queue Manager Memory Region R Control Registers The following sections describe each of the four register locations that may be present for each queue in the queues region. For reasons of implementation and area efficiency, these registers are not actually implemented as a huge array of flip flops but are instead implemented as a single set of mailbox registers which use the LSBs of the provided address as a queue index. Due to this implementation all accesses to these registers need to be performed as a single burst write for each packet push operation or a single burst read for each packet pop operation. The length of a burst to push or pop a packet will vary depending on the optional features that the queue supports which may be 4, 8, 12 or 16 bytes. Queue N Register D must always be written / read in the burst but the preceding words are optional depending on the required queue functionality.

### 16.5.7.27 QMEMRBASE4 Register (offset = 1040h) [reset = 0h]

QMEMRBASE4 is shown in [Figure 16-303](#) and described in [Table 16-317](#).

**Figure 16-303. QMEMRBASE4 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-317. QMEMRBASE4 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-5	REG	R/W-0	0	This field contains the base address of the memory region R.

**16.5.7.28 QMEMCTRL4 Register (offset = 1044h) [reset = 0h]**

 QMEMCTRL4 is shown in [Figure 16-304](#) and described in [Table 16-318](#).

**Figure 16-304. QMEMCTRL4 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-318. QMEMCTRL4 Register Field Descriptions**

Bit	Field	Type	Reset	Description
29-16	START_INDEX	R/W-0	0	This field indicates where in linking RAM does the descriptor linking information corresponding to memory region R starts.
11-8	DESC_SIZE	R/W-0	0	This field indicates the size of each descriptor in this memory region. It is an encoded value that specifies descriptor size as $2^{(5+desc\_size)}$ number of bytes. The settings of desc_size from 9-15 are reserved.
2-0	REG_SIZE	R/W-0	0	This field indicates the size of the memory region (in terms of number of descriptors). It is an encoded value that specifies region size as $2^{(5+reg\_size)}$ number of descriptors. Queue Manager Memory Region R Control Registers The following sections describe each of the four register locations that may be present for each queue in the queues region. For reasons of implementation and area efficiency, these registers are not actually implemented as a huge array of flip flops but are instead implemented as a single set of mailbox registers which use the LSBs of the provided address as a queue index. Bit	Field	Type	Reset	Description
31-5	REG	R/W-0	0	This field contains the base address of the memory region R.

**16.5.7.30 QMEMCTRL5 Register (offset = 1054h) [reset = 0h]**

 QMEMCTRL5 is shown in [Figure 16-306](#) and described in [Table 16-320](#).

**Figure 16-306. QMEMCTRL5 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-320. QMEMCTRL5 Register Field Descriptions**

Bit	Field	Type	Reset	Description
29-16	START_INDEX	R/W-0	0	This field indicates where in linking RAM does the descriptor linking information corresponding to memory region R starts.
11-8	DESC_SIZE	R/W-0	0	This field indicates the size of each descriptor in this memory region. It is an encoded value that specifies descriptor size as $2^{(5+desc\_size)}$ number of bytes. The settings of desc_size from 9-15 are reserved.
2-0	REG_SIZE	R/W-0	0	This field indicates the size of the memory region (in terms of number of descriptors). It is an encoded value that specifies region size as $2^{(5+reg\_size)}$ number of descriptors. Queue Manager Memory Region R Control Registers The following sections describe each of the four register locations that may be present for each queue in the queues region. For reasons of implementation and area efficiency, these registers are not actually implemented as a huge array of flip flops but are instead implemented as a single set of mailbox registers which use the LSBs of the provided address as a queue index. Due to this implementation all accesses to these registers need to be performed as a single burst write for each packet push operation or a single burst read for each packet pop operation. The length of a burst to push or pop a packet will vary depending on the optional features that the queue supports which may be 4, 8, 12 or 16 bytes. Queue N Register D must always be written / read in the burst but the preceding words are optional depending on the required queue functionality.

### 16.5.7.31 QMEMRBASE6 Register (offset = 1060h) [reset = 0h]

QMEMRBASE6 is shown in [Figure 16-307](#) and described in [Table 16-321](#).

**Figure 16-307. QMEMRBASE6 Register**

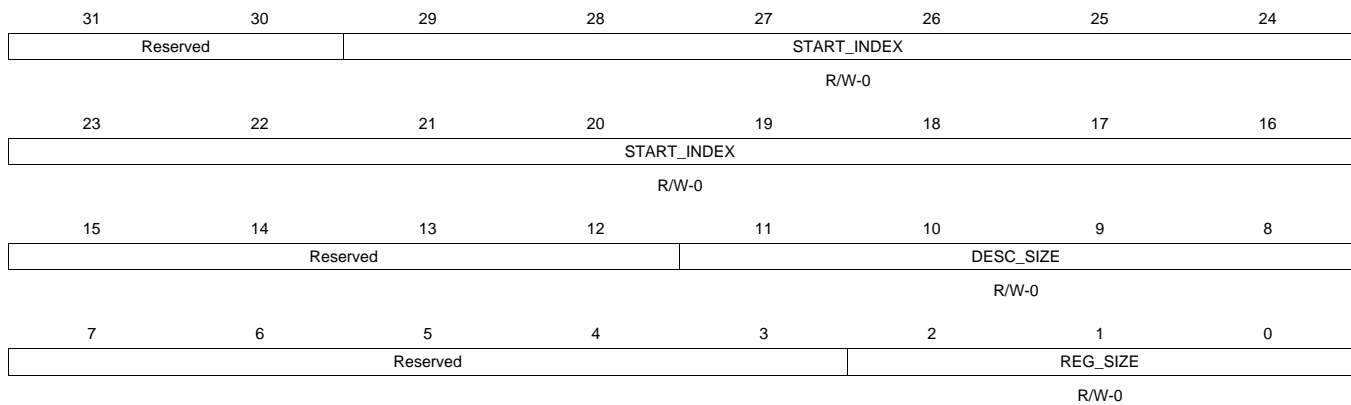

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-321. QMEMRBASE6 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-5	REG	R/W-0	0	This field contains the base address of the memory region R.

**16.5.7.32 QMEMCTRL6 Register (offset = 1064h) [reset = 0h]**

 QMEMCTRL6 is shown in [Figure 16-308](#) and described in [Table 16-322](#).

**Figure 16-308. QMEMCTRL6 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-322. QMEMCTRL6 Register Field Descriptions**

Bit	Field	Type	Reset	Description
29-16	START_INDEX	R/W-0	0	This field indicates where in linking RAM does the descriptor linking information corresponding to memory region R starts.
11-8	DESC_SIZE	R/W-0	0	This field indicates the size of each descriptor in this memory region. It is an encoded value that specifies descriptor size as $2^{(5+desc\_size)}$ number of bytes. The settings of desc_size from 9-15 are reserved.
2-0	REG_SIZE	R/W-0	0	This field indicates the size of the memory region (in terms of number of descriptors). It is an encoded value that specifies region size as $2^{(5+reg\_size)}$ number of descriptors. Queue Manager Memory Region R Control Registers The following sections describe each of the four register locations that may be present for each queue in the queues region. For reasons of implementation and area efficiency, these registers are not actually implemented as a huge array of flip flops but are instead implemented as a single set of mailbox registers which use the LSBs of the provided address as a queue index. Due to this implementation all accesses to these registers need to be performed as a single burst write for each packet push operation or a single burst read for each packet pop operation. The length of a burst to push or pop a packet will vary depending on the optional features that the queue supports which may be 4, 8, 12 or 16 bytes. Queue N Register D must always be written / read in the burst but the preceding words are optional depending on the required queue functionality.

### 16.5.7.33 QMEMRBASE7 Register (offset = 1070h) [reset = 0h]

QMEMRBASE7 is shown in [Figure 16-309](#) and described in [Table 16-323](#).

**Figure 16-309. QMEMRBASE7 Register**

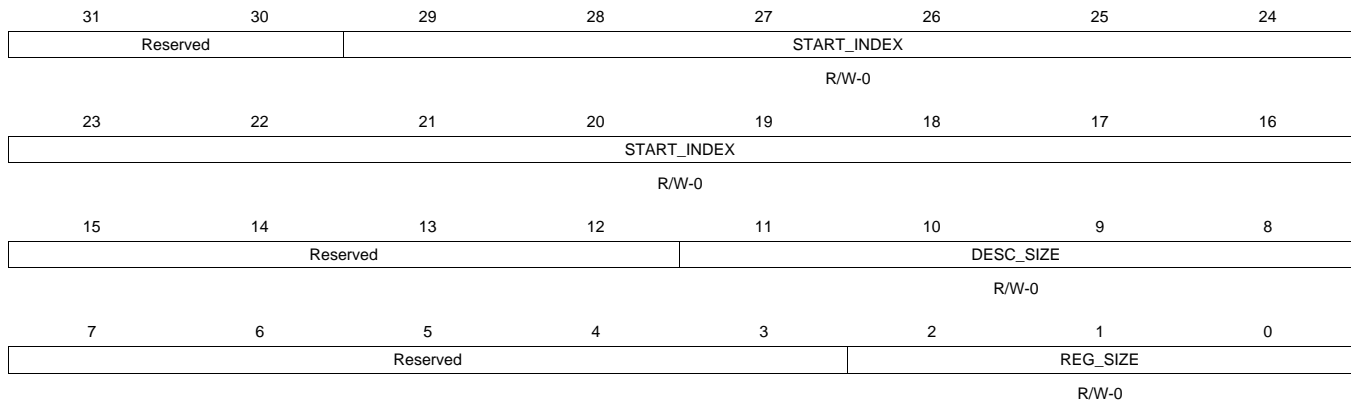

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-323. QMEMRBASE7 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-5	REG	R/W-0	0	This field contains the base address of the memory region R.

**16.5.7.34 QMEMCTRL7 Register (offset = 1074h) [reset = 0h]**

 QMEMCTRL7 is shown in [Figure 16-310](#) and described in [Table 16-324](#).

**Figure 16-310. QMEMCTRL7 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-324. QMEMCTRL7 Register Field Descriptions**

Bit	Field	Type	Reset	Description
29-16	START_INDEX	R/W-0	0	This field indicates where in linking RAM does the descriptor linking information corresponding to memory region R starts.
11-8	DESC_SIZE	R/W-0	0	This field indicates the size of each descriptor in this memory region. It is an encoded value that specifies descriptor size as $2^{(5+desc\_size)}$ number of bytes. The settings of desc_size from 9-15 are reserved.
2-0	REG_SIZE	R/W-0	0	This field indicates the size of the memory region (in terms of number of descriptors). It is an encoded value that specifies region size as $2^{(5+reg\_size)}$ number of descriptors. Queue Manager Memory Region R Control Registers The following sections describe each of the four register locations that may be present for each queue in the queues region. For reasons of implementation and area efficiency, these registers are not actually implemented as a huge array of flip flops but are instead implemented as a single set of mailbox registers which use the LSBs of the provided address as a queue index. Due to this implementation all accesses to these registers need to be performed as a single burst write for each packet push operation or a single burst read for each packet pop operation. The length of a burst to push or pop a packet will vary depending on the optional features that the queue supports which may be 4, 8, 12 or 16 bytes. Queue N Register D must always be written / read in the burst but the preceding words are optional depending on the required queue functionality.

### 16.5.7.35 QUEUE\_0\_A Register (offset = 2000h) [reset = 0h]

QUEUE\_0\_A is shown in [Figure 16-311](#) and described in [Table 16-325](#).

**Figure 16-311. QUEUE\_0\_A Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-325. QUEUE\_0\_A Register Field Descriptions**

Bit	Field	Type	Reset	Description
13-0	QUEUE_ENTRY_COUNT	R-0	0	This field indicates how many packets are currently queued on the queue. This count is incremented by 1 whenever a packet is added to the queue. This count is decremented by 1 whenever a packet is popped from the queue.

**16.5.7.36 QUEUE\_0\_B Register (offset = 2004h) [reset = 0h]**

QUEUE\_0\_B is shown in [Figure 16-312](#) and described in [Table 16-326](#).

**Figure 16-312. QUEUE\_0\_B Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-326. QUEUE\_0\_B Register Field Descriptions**

Bit	Field	Type	Reset	Description
27-0	QUEUE_BYTE_COUNT	R-0	0	This field indicates how many bytes total are contained in all of the packets which are currently queued on this queue.

**16.5.7.37 QUEUE\_0\_C Register (offset = 2008h) [reset = 0h]**

 QUEUE\_0\_C is shown in [Figure 16-313](#) and described in [Table 16-327](#).

**Figure 16-313. QUEUE\_0\_C Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-327. QUEUE\_0\_C Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	HEAD_TAIL	W-0	0	Head/Tail Push Control. Set to zero in order to push packet onto tail of queue and set to one in order to push packet onto head of queue.
13-0	PACKET_SIZE	R/W-0	0	packet_size This field indicates packet size and is assumed to be zero on each packet add unless the value is explicitly overwritten. This field indicates packet size for packet pop operation.

**16.5.7.38 QUEUE\_0\_D Register (offset = 200Ch) [reset = 0h]**

 QUEUE\_0\_D is shown in [Figure 16-314](#) and described in [Table 16-328](#).

**Figure 16-314. QUEUE\_0\_D Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-328. QUEUE\_0\_D Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W-0	0	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W-0	0	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

### 16.5.7.39 QUEUE\_1\_A Register (offset = 2010h) [reset = 0h]

QUEUE\_1\_A is shown in [Figure 16-315](#) and described in [Table 16-329](#).

**Figure 16-315. QUEUE\_1\_A Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-329. QUEUE\_1\_A Register Field Descriptions**

Bit	Field	Type	Reset	Description
13-0	QUEUE_ENTRY_COUNT	R-0	0	This field indicates how many packets are currently queued on the queue. This count is incremented by 1 whenever a packet is added to the queue. This count is decremented by 1 whenever a packet is popped from the queue.

**16.5.7.40 QUEUE\_1\_B Register (offset = 2014h) [reset = 0h]**

QUEUE\_1\_B is shown in [Figure 16-316](#) and described in [Table 16-330](#).

**Figure 16-316. QUEUE\_1\_B Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-330. QUEUE\_1\_B Register Field Descriptions**

Bit	Field	Type	Reset	Description
27-0	QUEUE_BYTE_COUNT	R-0	0	This field indicates how many bytes total are contained in all of the packets which are currently queued on this queue.

**16.5.7.41 QUEUE\_1\_C Register (offset = 2018h) [reset = 0h]**

 QUEUE\_1\_C is shown in [Figure 16-317](#) and described in [Table 16-331](#).

**Figure 16-317. QUEUE\_1\_C Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-347. QUEUE\_5\_C Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	HEAD_TAIL	W-0	0	Head/Tail Push Control. Set to zero in order to push packet onto tail of queue and set to one in order to push packet onto head of queue.
13-0	PACKET_SIZE	R/W-0	0	packet_size This field indicates packet size and is assumed to be zero on each packet add unless the value is explicitly overwritten. This field indicates packet size for packet pop operation.

**16.5.7.58 QUEUE\_5\_D Register (offset = 205Ch) [reset = 0h]**

 QUEUE\_5\_D is shown in [Figure 16-334](#) and described in [Table 16-348](#).

**Figure 16-334. QUEUE\_5\_D Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-348. QUEUE\_5\_D Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W-0	0	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W-0	0	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

**16.5.7.59 QUEUE\_6\_A Register (offset = 2060h) [reset = 0h]**

 QUEUE\_6\_A is shown in [Figure 16-335](#) and described in [Table 16-349](#).

**Figure 16-335. QUEUE\_6\_A Register**

**Table 16-375. QUEUE\_12\_C Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	HEAD_TAIL	W-0	0	Head/Tail Push Control. Set to zero in order to push packet onto tail of queue and set to one in order to push packet onto head of queue.
13-0	PACKET_SIZE	R/W-0	0	packet_size This field indicates packet size and is assumed to be zero on each packet add unless the value is explicitly overwritten. This field indicates packet size for packet pop operation.

**16.5.7.86 QUEUE\_12\_D Register (offset = 20CCh) [reset = 0h]**

 QUEUE\_12\_D is shown in [Figure 16-362](#) and described in [Table 16-376](#).

**Figure 16-362. QUEUE\_12\_D Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-376. QUEUE\_12\_D Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W-0	0	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W-0	0	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

27-0	QUEUE_BYTE_COUNT	R-0	0	This field indicates how many bytes total are contained in all of the packets which are currently queued on this queue.

**16.5.7.113 QUEUE\_19\_C Register (offset = 2138h) [reset = 0h]**

QUEUE\_19\_C is shown in [Figure 16-389](#) and described in [Table 16-403](#).

**Figure 16-389. QUEUE\_19\_C Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-403. QUEUE\_19\_C Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	HEAD_TAIL	W-0	0	Head/Tail Push Control. Set to zero in order to push packet onto tail of queue and set to one in order to push packet onto head of queue.
13-0	PACKET_SIZE	R/W-0	0	packet_size This field indicates packet size and is assumed to be zero on each packet add unless the value is explicitly overwritten. This field indicates packet size for packet pop operation.

**16.5.7.114 QUEUE\_19\_D Register (offset = 213Ch) [reset = 0h]**

 QUEUE\_19\_D is shown in [Figure 16-390](#) and described in [Table 16-404](#).

**Figure 16-390. QUEUE\_19\_D Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-404. QUEUE\_19\_D Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W-0	0	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W-0	0	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

**16.5.7.115 QUEUE\_20\_A Register (offset = 2140h) [reset = 0h]**

**Table 16-431. QUEUE\_26\_C Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	HEAD_TAIL	W-0	0	Head/Tail Push Control. Set to zero in order to push packet onto tail of queue and set to one in order to push packet onto head of queue.
13-0	PACKET_SIZE	R/W-0	0	packet_size This field indicates packet size and is assumed to be zero on each packet add unless the value is explicitly overwritten. This field indicates packet size for packet pop operation.

**16.5.7.142 QUEUE\_26\_D Register (offset = 21ACh) [reset = 0h]**

 QUEUE\_26\_D is shown in [Figure 16-418](#) and described in [Table 16-432](#).

**Figure 16-418. QUEUE\_26\_D Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-432. QUEUE\_26\_D Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W-0	0	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W-0	0	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

4-0	DESC_SIZE	R/W-0	0	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

**Table 16-512. QUEUE\_46\_D Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W-0	0	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W-0	0	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

**16.5.7.223 QUEUE\_47\_A Register (offset = 22F0h) [reset = 0h]**

Bit	Field	Type	Reset	Description
31	HEAD_TAIL	W-0	0	Head/Tail Push Control. Set to zero in order to push packet onto tail of queue and set to one in order to push packet onto head of queue.
13-0	PACKET_SIZE	R/W-0	0	packet_size This field indicates packet size and is assumed to be zero on each packet add unless the value is explicitly overwritten. This field indicates packet size for packet pop operation.

**16.5.7.250 QUEUE\_53\_D Register (offset = 235Ch) [reset = 0h]**

 QUEUE\_53\_D is shown in [Figure 16-526](#) and described in [Table 16-540](#).

**Figure 16-526. QUEUE\_53\_D Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-540. QUEUE\_53\_D Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W-0	0	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W-0	0	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

QUEUE\_60\_C is shown in [Figure 16-553](#) and described in [Table 16-567](#).

**Figure 16-553. QUEUE\_60\_C Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-567. QUEUE\_60\_C Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	HEAD_TAIL	W-0	0	Head/Tail Push Control. Set to zero in order to push packet onto tail of queue and set to one in order to push packet onto head of queue.
13-0	PACKET_SIZE	R/W-0	0	packet_size This field indicates packet size and is assumed to be zero on each packet add unless the value is explicitly overwritten. This field indicates packet size for packet pop operation.

**16.5.7.278 QUEUE\_60\_D Register (offset = 23CCh) [reset = 0h]**

 QUEUE\_60\_D is shown in [Figure 16-554](#) and described in [Table 16-568](#).

**Figure 16-554. QUEUE\_60\_D Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-568. QUEUE\_60\_D Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W-0	0	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W-0	0	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-596. QUEUE\_67\_D Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W-0	0	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W-0	0	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

4-0	DESC_SIZE	R/W-0	0	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

**Table 16-676. QUEUE\_87\_D Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W-0	0	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W-0	0	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

**16.5.7.387 QUEUE\_88\_A Register (offset = 2580h) [reset = 0h]**

Bit	Field	Type	Reset	Description
31	HEAD_TAIL	W-0	0	Head/Tail Push Control. Set to zero in order to push packet onto tail of queue and set to one in order to push packet onto head of queue.
13-0	PACKET_SIZE	R/W-0	0	packet_size This field indicates packet size and is assumed to be zero on each packet add unless the value is explicitly overwritten. This field indicates packet size for packet pop operation.

**16.5.7.414 QUEUE\_94\_D Register (offset = 25ECh) [reset = 0h]**

 QUEUE\_94\_D is shown in [Figure 16-690](#) and described in [Table 16-704](#).

**Figure 16-690. QUEUE\_94\_D Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-704. QUEUE\_94\_D Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W-0	0	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W-0	0	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

QUEUE\_101\_C is shown in [Figure 16-717](#) and described in [Table 16-731](#).

**Figure 16-717. QUEUE\_101\_C Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-731. QUEUE\_101\_C Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	HEAD_TAIL	W-0	0	Head/Tail Push Control. Set to zero in order to push packet onto tail of queue and set to one in order to push packet onto head of queue.
13-0	PACKET_SIZE	R/W-0	0	packet_size This field indicates packet size and is assumed to be zero on each packet add unless the value is explicitly overwritten. This field indicates packet size for packet pop operation.

**16.5.7.442 QUEUE\_101\_D Register (offset = 265Ch) [reset = 0h]**

 QUEUE\_101\_D is shown in [Figure 16-718](#) and described in [Table 16-732](#).

**Figure 16-718. QUEUE\_101\_D Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-732. QUEUE\_101\_D Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W-0	0	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W-0	0	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

**Table 16-757. QUEUE\_108\_A Register Field Descriptions**

Bit	Field	Type	Reset	Description
13-0	QUEUE_ENTRY_COUNT	R-0	0	This field indicates how many packets are currently queued on the queue. This count is incremented by 1 whenever a packet is added to the queue. This count is decremented by 1 whenever a packet is popped from the queue.

**16.5.7.468 QUEUE\_108\_B Register (offset = 26C4h) [reset = 0h]**

QUEUE\_108\_B is shown in [Figure 16-744](#) and described in [Table 16-758](#).

**Figure 16-744. QUEUE\_108\_B Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-758. QUEUE\_108\_B Register Field Descriptions**

Bit	Field	Type	Reset	Description
27-0	QUEUE_BYTE_COUNT	R-0	0	This field indicates how many bytes total are contained in all of the packets which are currently queued on this queue.

**16.5.7.469 QUEUE\_108\_C Register (offset = 26C8h) [reset = 0h]**

QUEUE\_108\_C is shown in [Figure 16-745](#) and described in [Table 16-759](#).

**Figure 16-745. QUEUE\_108\_C Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-759. QUEUE\_108\_C Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	HEAD_TAIL	W-0	0	Head/Tail Push Control. Set to zero in order to push packet onto tail of queue and set to one in order to push packet onto head of queue.
13-0	PACKET_SIZE	R/W-0	0	packet_size This field indicates packet size and is assumed to be zero on each packet add unless the value is explicitly overwritten. This field indicates packet size for packet pop operation.

**16.5.7.470 QUEUE\_108\_D Register (offset = 26CCh) [reset = 0h]**

 QUEUE\_108\_D is shown in [Figure 16-746](#) and described in [Table 16-760](#).

**Figure 16-746. QUEUE\_108\_D Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-760. QUEUE\_108\_D Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W-0	0	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W-0	0	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

**16.5.7.471 QUEUE\_109\_A Register (offset = 26D0h) [reset = 0h]**

However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-812. QUEUE\_121\_D Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W-0	0	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W-0	0	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

**16.5.7.523 QUEUE\_122\_A Register (offset = 27A0h) [reset = 0h]**

QUEUE\_122\_A is shown in [Figure 16-799](#) and described in [Table 16-813](#).

 QUEUE\_128\_C is shown in [Figure 16-825](#) and described in [Table 16-839](#).

**Figure 16-825. QUEUE\_128\_C Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-839. QUEUE\_128\_C Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	HEAD_TAIL	W-0	0	Head/Tail Push Control. Set to zero in order to push packet onto tail of queue and set to one in order to push packet onto head of queue.
13-0	PACKET_SIZE	R/W-0	0	packet_size This field indicates packet size and is assumed to be zero on each packet add unless the value is explicitly overwritten. This field indicates packet size for packet pop operation.

**16.5.7.550 QUEUE\_128\_D Register (offset = 280Ch) [reset = 0h]**

 QUEUE\_128\_D is shown in [Figure 16-826](#) and described in [Table 16-840](#).

**Figure 16-826. QUEUE\_128\_D Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-840. QUEUE\_128\_D Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W-0	0	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W-0	0	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

**16.5.7.551 QUEUE\_129\_A Register (offset = 2810h) [reset = 0h]**

 QUEUE\_129\_A is shown in [Figure 16-827](#) and described in [Table 16-841](#).

**Figure 16-827. QUEUE\_129\_A Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-841. QUEUE\_129\_A Register Field Descriptions**

Bit	Field	Type	Reset	Description
13-0	QUEUE_ENTRY_COUNT	R-0	0	This field indicates how many packets are currently queued on the queue. This count is incremented by 1 whenever a packet is added to the queue. This count is decremented by 1 whenever a packet is popped from the queue.

**16.5.7.552 QUEUE\_129\_B Register (offset = 2814h) [reset = 0h]**

QUEUE\_129\_B is shown in [Figure 16-828](#) and described in [Table 16-842](#).

**Figure 16-828. QUEUE\_129\_B Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-842. QUEUE\_129\_B Register Field Descriptions**

Bit	Field	Type	Reset	Description
27-0	QUEUE_BYTE_COUNT	R-0	0	This field indicates how many bytes total are contained in all of the packets which are currently queued on this queue.

**16.5.7.553 QUEUE\_129\_C Register (offset = 2818h) [reset = 0h]**

QUEUE\_129\_C is shown in [Figure 16-829](#) and described in [Table 16-843](#).

**Figure 16-829. QUEUE\_129\_C Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 16-843. QUEUE\_129\_C Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	HEAD_TAIL	W-0	0	Head/Tail Push Control. Set to zero in order to push packet onto tail of queue and set to one in order to push packet onto head of queue.
